Abstract: We study the problem of key generation for secure many to many communications. The problem is raised by the proliferation of large scale distributed file system supporting parallel access to multiple storage devices. Our work focuses on current Internet standards for such file systems, i.e. the parallel Network File System (pNFS), which makes use of Kerberos to establish parallel session keys between client and storage devices. Our review of the existing Kerberos-based protocol has a number of limitations: (i) a metadata server facilitating key exchange between clients and storage devices has heavy workload which restricts the scalability of the protocol; (ii) the protocol does not provide forward secrecy; (iii) metadata server establish itself all the session keys that are used between the clients and storage devices, and this inherently leads to the key escrow. In this paper, we propose a variety of authenticated key exchange protocols that are designed to address above issues. We show that our protocols are capable of reducing up to approximately 54% of workload of a metadata server and concurrently supporting forward secrecy and escrow-freeness.

Keywords: Parallel sessions, authenticated key exchange, network file systems(NFS), forward secrecy, key escrow.

I. Introduction

In parallel file systems, the file data is distributed across multiple storage devices or nodes to allow concurrent access by multiple tasks of a parallel application. That is typically used in large scale cluster computing that focuses on high performance and reliable fetch to large datasets [4]. That higher I/O bandwidth is achieved through concurrent fetching data to multiple storage devices within large computing clusters, while data loss is protected through data mirroring using defect tolerant striping algorithms [6]. Few examples of high performance parallel file systems that are in the production use are the IBM General Parallel Files System. which are usually required for advanced scientific or data intensive applications such as digital animation studios, computational fluid dynamics, and semiconductor manufacturing. In these environments, hundreds or thousands of file system clients share data and generate very much high aggregate I/O load on the file system supporting petabytes or terabytes scale storage capacities [1][8]. Independent of the development of the cluster and high performance computing, the emergence of clouds and the MapReduce programming model has resulted in file system such as the Hadoop Distributed File System (HDFS) [2]. We provide some background on pNFS and describe its existing security mechanisms associated with secure communications between clients and distributed storage devices [3]. Moreover, we identify the limitations of the current Kerberos-based protocol in pNFS for establishing secure channels in parallel. The main results of this paper are three new provably secure authenticated key exchange protocols [7] [9]. Our protocols, progressively designed to achieve each of the above properties, demonstrate the trade-offs between efficiency and security. We show that our protocols can reduce the workload of the metadata server by approximately half compared to the current Kerberos-based protocol, while achieving the desired security properties and keeping the computational overhead at the clients and the storage devices at a reasonably low level [5]. We define an appropriate security model and prove that our protocols are secure in the model.

In this work, we investigate the issue of the secure many to many communications in the large scale network file systems which support parallel fetch to multiple storing devices. That we considering the communication model where there are a large number of the clients accessing multiple remote and distributed storage devices in parallel. Particularly, we tries to focus on how to exchange the key materials and establishment of the parallel secure sessions between clients and storage devices in the parallel Network File System (pNFS), the current Internet standards in efficient and scalable manner [9].
II. Related Work

Telecare Medical Information Systems (TMIS) provide an effective way to improve the medical process between doctors, nurses and patients. By improving the security and privacy of TMIS, it is important while challenging to improve the TMIS so that a patient and a doctor can perform synchronized authentication and session key establishment using a 3-party medical server while the secure data of the patient can be ensured.

In proposed system an anonymous three-party password authenticated key exchange (3PAKE) protocol for TMIS is used. The protocol is based on the efficient elliptic curve cryptosystem. For security, we apply the pi calculus based formal verification tool ProVerif to show that our 3PAKE protocol for TMIS can provide anonymity for patient and doctor as well as achieves synchronized authentication and session key security. The advantage of proposed scheme is security and efficiency that can be used in TMIS. For this J-PAKE based protocols are used. The disadvantage of proposed scheme is of it reduced session keys.

Password-based encrypted key exchange are protocols that are designed to provide pair of users communicating over an unreliable channel with a secure session key even when the secret key or password shared between two users is drawn from a small set of keys. In proposed scheme, two simple passwords based encrypted key exchange protocols based on that of Bellovin and Merritt. While one protocol is more suitable to scenarios in which the password is shared across multiple servers, the other provides better security. Both protocols are as efficient, if not better, as any of the existing encrypted key exchange protocols in the literature, and yet they only require a single random oracle instance. The proof of security for both protocols is in the random oracle model and based on hardness of the computational Diffie-Hellman problem. However, some of the techniques that we use are quite different from the usual ones and make use of new variants of the Diffie-Hellman problem, which are of independent interest. We also provide concrete relations between the new variants and the standard Diffie-Hellman problem. Advantage of this scheme it is possible to find several flavors of key. In this different types of protocols are used like SIGMA, IKE etc.

Passwords are one of the most common causes of system crashes, because the low entropy of passwords makes systems vulnerable to brute force guessing attacks. Due to new technology passwords can be hacked easily. Automated Turing Tests continue to be an effective, easy-to-deploy approach to identify automated malicious login attempts with reasonable cost of inconvenience to users. Hence in this proposed scheme the inadequacy of existing and proposed login protocols designed to address large-scale online dictionary attacks e.g. from a botnet of hundreds of thousands of nodes. In this scheme proposed a simple scheme that strengthens password based authentication protocols and helps prevent online dictionary attacks as well as many-to-many attacks common to 3-pass SPAKA protocols.

Proposed scheme Uses compositional method for proving cryptographically sound security properties of key exchange protocols, based on a symbolic logic that is interpreted over conventional runs of a protocol against a probabilistic polynomial time attacker. Since reasoning about an unbounded number of runs of a protocol involves induction-like arguments about properties preserved by each run, we formulate a specification of secure key exchange that, unlike conventional key in distinguish ability, is closed under general composition with steps that use the key. We present formal proof rules based on this game-based condition, and prove that the proof rules are sound over a computational semantics.

In a public network, when a number of clusters connected to each other is increased becomes a potential threat to security applications running on the clusters. To address this problem, a Message Passing Interface (MPI) is developed to preserve security services in an unsecured network. The proposed work focuses on MPI rather than other protocols because MPI is one of the most popular communication protocols on distributed clusters. Here AES algorithm is used for encryption/decryption and interpolation polynomial algorithm is used for key management which is then integrated into Message Passing Interface Chameleon version 2 (MPICH2) with standard MPI interface that becomes ES-MPICH2. This ES-MPICH2 is a new MPI that provides security and authentication for distributed clusters which is unified into cryptographic and mathematical concept. The major desire of ES-MPICH2 is supporting a large variety of computation and communication platforms. The proposed system is based on both cryptographic and mathematical concept which leads to full of error free message passing interface with enhanced security.

Password Authenticated Key Exchange (PAKE) is one of the important topics in cryptography. It aims to address a practical security problem: how to establish secure communication between two parties solely based
on a shared password without requiring a Public Key Infrastructure (PKI). After more than a decade of extensive research in this field, there have been several PAKE protocols available. The EKE and SPEKE schemes are perhaps the two most notable examples. Both techniques are however patented. In this paper, we review these techniques in detail and summarize various theoretical and practical weaknesses. In addition, we present a new PAKE solution called J-PAKE. Our strategy is to depend on well-established primitives such as the Zero-Knowledge Proof (ZKP). So far, almost all of the past solutions have avoided using ZKP for the concern on efficiency. We demonstrate how to effectively integrate the ZKP into the protocol design and meanwhile achieve good efficiency. Our protocol has comparable computational efficiency to the EKE and SPEKE schemes with clear advantages on security.

We present a mechanized proof of the password-based protocol One-Encryption Key Exchange (OEKE) using the computationally-sound protocol prover CryptoVerif. OEKE is a non-trivial protocol, and thus mechanizing its proof provides additional confidence that it is correct. This case study was also an opportunity to implement several important extensions of CryptoVerif, useful for proving many other protocols. We have extended CryptoVerif to support the computational Diffie-Hellman assumption. We have also added support for proofs that rely on Shoup’s lemma and additional game transformations. In particular, we improve over the standard computation of probabilities when Shoup’s lemma is used, which allows us to improve the bound given in a previous manual proof of OEKE, and to show that the adversary can test at most one password per session of the protocol. In this paper, we present these extensions, with their application to the proof of OEKE. All steps of the proof, both automatic and manually guided, are verified by CryptoVerif.

-Bruno Blanchet [7]

Password-Authenticated Key Exchange (PAKE) studies how to establish secure communication between two remote parties solely based on their shared password, without requiring a Public Key Infrastructure (PKI). Despite extensive research in the past decade, this problem remains unsolved. Patent has been one of the biggest brakes in deploying PAKE solutions in practice. Besides, even for the patented schemes like EKE and SPEKE, their security is only heuristic; researchers have reported some subtle but worrying security issues. In this paper, we propose to tackle this problem using an approach different from all past solutions. Our protocol, Password Authenticated Key Exchange by Juggling (J-PAKE), achieves mutual authentication in two steps: first, two parties send ephemeral public keys to each other; second, they encrypt the shared password by juggling the public keys in a variable way. The first use of such a juggling technique was seen in solving the Dining Cryptographers problem in 2006. Here, we apply it to solve the PAKE problem, and show that the protocol is zero-knowledge as it reveals nothing except one-bit information: whether the supplied passwords at two sides are the same. With clear advantages in security, our scheme has comparable efficiency to the EKE and SPEKE protocols.

III. Proposed System

![System Architecture](image)

Fig 1: System Architecture
User and Server Authentication: Kerberos, a widely deployed network authentication protocol supported by all major operating systems, allows nodes communicating over a non-secure network to perform mutual authentication as mentioned in fig [1]. Secure storage access: The session key generated by the ticket-granting server (metadata server) for a client and a storage device during single sign-on can then be used in the storage access protocol. It protects the integrity and privacy of data transmitted between the client and the storage device. Clearly, the session key and the associated layout are valid only within the granted validity period. Particularly, we attempt to meet the following desirable properties, which have not been satisfactorily achieved or are not achievable by current Kerberos-based solution. More specifically, pNFS comprises a collection of three protocols: (i) the pNFS protocol that transfers file metadata, also known as a layout, between the metadata server and a client node; (ii) the storage access protocol that specifies how the client accesses data from the associated storage devices according to the corresponding metadata; and (iii) the control protocol that synchronizes the state between the metadata server and the storage devices.

IV. System Flow

We have introduced metadata in our work as mentioned below in fig [2], metadata plays a vital role in managing the client operation. Metadata performs the major task of authentication of user. It generates One-Time-Password (OTP) to authenticate the user access. Once the user/client gets verified the metadata create session key which enables user to access resources for specific period of time.

Algorithm

Upon receiving an I/O request for a file object from C, each Si performs the following:
1. check if the layout σi is valid;
2. decrypt the authentication token and recover key KCSi;
3. compute keys skz i = F(KCSi;IDC,IDSi,v,sid,z) for z = 0, 1;
4. decrypt the encrypted message, check if IDC matches the identity of C and if t is within the current validity period v;
5. if all previous checks pass, Si replies C with a key confirmation message using key sk0 i .

- In first step we are checking if available layout is valid or not for further operations and communication.
- In second step we do the decryption operation on the token which is generated by metadata server for authentication process. By performing decryption we will recover the key for client set.
- In this third step we will compute the key for storage set for accessing the data/information within the storage set. We will compute key by checking the key of client set as well as id for users. As per the result we will return access to user or denied to communicate.
- Fourth step will perform the task of decryption of encrypted message. And it will also check for validation for user access.
- In this final step if all the above process is successfully validated then it will return key confirmation message to User/client.

V. Conclusion & Future Scope

We proposed three authenticated key exchange protocols for parallel network file system (pNFS). Our protocols offer the advantages over the existing Kerberos-based pNFS protocol. First, the metadata server…
executing our protocols has much lower workload than that of the Kerberos-based approach. Second, two our protocols provide forward secrecy: one is partially forward secure (with respect to the multiple sessions within a time period), while the other is fully forward secure (with respect to a session). Third, we have designed a protocol which not only provides forward secrecy, but is also escrow-free.

Acknowledgement

We would like to thank Prof. P. V. Nagare, vice-principal at KVNNIEER Nashik, for his valuable guidance. We wish to express our sincere gratitude to Prof. N. V. Kapade, project coordinator for his encouragement in carrying out this project work. We also wish to express our gratitude to the all lecturers of KVNNIEER who render their support during the period of project work.
