Abstract

Background: Mechanical Ventilation (MV) has become frequently used life-supportive management in Pediatric Intensive Care Units (PICU). But very little data is available from developing countries regarding the outcome analysis coupled with demographic status and clinical details which is a challenge for the modern day intensivists.

Objective: To determine the characteristics and outcome of ventilated patients in the paediatric medical intensive care unit in a tertiary care teaching hospital, Telangana.

Methods: A prospective descriptive study was conducted on ventilated children admitted to PICU from July to December 2015. The factors studied included demographic and clinical profile, length of stay on ventilator, indications for ventilation and the final outcome.

Results: A total of 144 (23%) cases admitted in PICU were ventilated over the period of six months. Male to female ratio was 1.36:1. Neurological (27.8%) and respiratory (25.6%) causes were found to be the commonest indicators of ventilation in the study. The average ventilator stay was 2.4 days and hospital stay was 9.71 days. 51% of ventilated cases were infants and 81% of total deaths occurred under five years age group. 49.3% of ventilated cases were successfully discharged and neurological cases had a better outcome (64%) among all the cases.

Conclusion: This study provides an insight into the present status of PICU in a government tertiary teaching hospital analyses the limitations and recommends the need to strengthen PICU to improve the quality care for the better survival of critically ill children.

Key Words: Indications, Mechanical Ventilation, Outcome, PICU, Ventilator stay.

I. Introduction

With the advancement in intensive care facilities, there is a dramatic increase in survival of critically ill children. Previous studies have shown significant positive impact of Intensive Care Unit (ICU) physicians on the outcome in children and adults¹,². ICU is also one of the sites where medical errors are most likely to occur because of the complexity of the diseases and patients are vulnerable to experience adverse outcomes due to multiple interventions³,⁴. Hence, it is obligatory for the intensivists to scrutinize the events occurring in the PICU and outcome of mechanically ventilated children for improving the quality care of the critically ill children.

Mechanical Ventilation (MV) is a life-supporting device, invasive technology of intensive care unit, to mimic the respiratory physiological function at the time of either impending or acute respiratory failure⁵. The percentage of children receiving mechanical ventilation in PICUs ranges from 17 -64% in developed countries where PICUs are mature and established discipline of medicine⁶-¹⁰. But very little data is available from Asian countries regarding use of MV in PICUs.¹¹-¹³

Niloufer hospital for women and children is a 500 bedded paediatric teaching hospital located in Hyderabad in the state of Telangana and is one of the largest government pediatric hospitals in the country. Thirteen beds have been allocated to the paediatric medical intensive care unit (PICU). The PICU is staffed by two consultant pediatricians, one pediatric senior registrar and 4 residents. They are responsible for covering the PICU 24 hours a day and handling ventilators with back up support from biomedical engineer. Nurse to patient ratio is 1:4. Admission of a child to PICU is decided by the consultants. The number of patients ventilated in the PICU averages 20 to 25 per month. The PICU is supported by a lab which provides services round the clock. The current study is intended to provide a baseline status of outcome of ventilated cases and also serves to
compare with other paediatric intensive care units. This study was intended to pursue the gaps and the data provided can be utilized by the hospital authorities to develop strategies for improving PICU.

II. Materials And Methods

A prospective descriptive clinical study was conducted in the PICU from July to December 2015 for a period of six months. We consecutively collected data from the case sheets of all ventilated paediatric patients till discharge or death. All the patients admitted for invasive ventilation during the study period were included irrespective of the source of admission i.e. transfer from a peripheral hospital or from wards of Niloufer hospital itself. In case of readmission, the patient was recorded only during the first admission. On recovery; patients were transferred to step down unit and later to pediatric wards. The following data were collected: age, gender; final diagnosis, co morbidities, treatment characteristics, length of stay on ventilator, length of stay in hospital and the outcome. Serial clinical and radiological assessments of patients included thorough physical examination, pulse oxymetry, arterial blood gas analysis and chest roentgenograms. Along with this the patients were investigated and treated for the primary diagnosis as per requirement of the case. Patients were followed till death or discharge from the hospital.

2.1 Statistical analysis:

Data was collected on a structured proforma designed and entered into Excel sheet. SPSS version 19 was used for statistical analysis. Descriptive statistics like mean, median, standard deviation and proportions were calculated for all the variables. To study the association of outcome with other variables chi square test was used. To compare mean value of ventilator stay in hours to outcome ANOVA with post hoc test of LSD (Least Significance Difference) was used. p value < 0.05 was considered significant.

III. Results

During the period of the study, the total number of patients admitted to PICU was 627. Of which 144 (23%) were ventilated. Out of 144 ventilated cases 83 were males and 61 were females. The male to female ratio was 1.36: 1.

![Chart 1: Sex distribution in the study](image)

The mean age of children put on ventilator was found to be 3.05 years. The indications for ventilation are shown in Table 1. Neurological (27.8%) and respiratory (25.6%) causes were found to be the commonest indicators of ventilation in the study.

The mean ventilator stay was 2.4 days and hospital stay was 9.71 days. The mean stay on ventilator for discharges was 76.3 hours and deaths were 43.05 hours. The mean for duration of stay was 13.82 days for discharges and 5.42 days for deaths.

Out of 144 ventilated cases, 71(49.3%) were discharged, 10(6.9%) cases Left Against Medical Advice (LAMA) and 63(43.8%) cases died.

Chart 2: Outcome of the ventilated cases

In the present study, 73(51%) ventilated cases were infants (1 month to 1 year), 41(28%) were between 1 to 5 years and 30cases (21%)belonged to age group of more than 5 years. Out of 73 infants, 38 (52%) were discharged and 32 (44%) died. Out of total 63 deaths, 51(81%) occurred in children under five years.

Chart 3: Relationship between the outcome and age of the ventilated babies

Mortality was significantly more for cases of Hepatic encephalopathy, DKA, MODS, Congenital heart diseases and Poisonings. Neurological cases had a better outcome (64%) among all the cases. MODS on admission had 73% mortality. Table.3 depicts the relationship between diagnosis and outcome of the patients in the study.

A Prospective Study On Clinical Profile And Outcome Of Ventilated Children In A Pediatric Intensive Care Unit

* Include causes like diabetic ketoacidosis, complicated gastroenteritis, status asthmaticus, renal, hematological, metabolic, post-operative surgical cases etc.

Out of 144 cases, 44 (30%) cases were on ventilator for less than 24 hours, 96 (67%) had ventilator stay between 1 to 7 days and only 4 (3%) cases had a prolonged stay between 8 to 30 days. A mortality rate of 82% was found in cases put under ventilator for less than 24 hours which was statistically significant (p < 0.05), while 70% of cases with a ventilator stay between 1 to 7 days were successfully discharged.

IV. Discussion

The percentage of admissions to PICU requiring Mechanical Ventilation (MV) in our study was 23% as found in study done in Pakistan by Shaukat F et al. But in the recent studies done by Vijayakumaryetal in 2012, 52% of children received MV in PICU of Sri Lanka and 50.7% in study done by Mukhtar B et al. in 2014 in Pakistan. Wolflier et al. reported that 34.6% of PICU admission in Italy required MV for >24hrs. Khemani et al. published that 30% of children in a cross-section of United States PICUs were mechanically ventilated.

The mean age of ventilated cases was 3 years and infants constituted the majority of cases; a similar phenomenon was appreciated in related studies. Both neurological (27.8%) and respiratory (25.6%) causes were found to be the commonest indicators of ventilation in the study. In few studies, acute neurological illness was found the major indications while several others reported that respiratory failure due to respiratory illness was the most common indication of MV in PICUs.

The most commonly used ventilatory mode was synchronized intermittent mandatory ventilation (SIMV) and several published reports also found that SIMV was commonly used as initial mode. The duration of mechanical ventilation was 4-6 days in few published reports. The average length of mechanical ventilation in our PICU was 2.4 days (range from 2 hours to 20 days).

The mortality rate of ventilated children was 43.8%. Shaukat et al. and Kendiril et al. reported the survival rate were 63% and 58.3% from Pakistan and Turkey respectively in the past. Vijayakumary et al. reported 27.6% mortality rate among mechanically ventilated patients. In developed countries, the overall mortality rates in mechanically ventilated patients in PICUs were less than 2%.

This audit recognised several reasons for higher mortality in the ventilated children. Lack of adequate nursing staff in the PICU, with the nurse to patient ratio 1:4 when compared to the required 1:1 ratio in the PICU was found to be one of the significant contributing factors. Several reports have shown that full-time trained critical care specialists in both adult and paediatric ICUs improve the quality of care and are associated with lower mortality and morbidity rates. Lack of trained pediatric intensivists, respiratory therapist services and regular trainings on MV were also identified as drawbacks in our set up. Selection of cases needs to be emphasized so that children must be put on ventilator before respiratory failure becomes clinically evident. In the present study, 82% mortality was noted in the ventilated cases with PICU stay less than or equal to 24 hours indicating very high mortality among patients who were put on mechanical ventilation for short periods of time, probably for terminal care. Patients were referred from faraway places and were admitted in poor status on admission. Hencedelayed presentation with multiorgan dysfunction syndrome was also found to be important cause of higher mortality in the present study. Non-affordability of the exorbitant costs of PICU care in corporate hospitals even by middle class population has tremendously increased the case load over government tertiary care teaching hospital. It is therefore mandatory on part of government to establish PICU in every district and strengthen the existing PICUs to cater to the needs of larger population.
V. Conclusion

Pediatric Intensive Care is a distinct but still novice speciality in developing countries requiring dedicated experienced staff along with modern equipment and 24/7 availability of advanced laboratory services like ABGs and emergency medicines. Mechanical ventilation is one of the major supportive modalities used in critical care all over the world, but this treatment modality is being used in very limited number of sick children in few government tertiary care medical centres. Despite the limitations of a greater percentage of critically sick children arriving late, the overall survival is 49 %. To improve the outcome of MV children in PICUs, we need effective, organized and structured educational courses from basic concept to clinical application for all physicians and nurses involved in the care of critically ill children receiving mechanical ventilation. As we gain experience in the ventilation our complications rate and mortality related to mechanical ventilation would also decrease hopefully.
