Varma Gottumukkala ${ }^{4}$<br>${ }^{1,2,3}$ Dept. of Electronics and Communication Engineering, College of Engineering (A), Andhra University, Visakhapatnam, Andhra Pradesh, India<br>${ }^{4}$ Senior Engineer, Qualcomm, U.S.A

#### Abstract

It is well known that the slots in the broad wall of rectangular waveguide along the axis do not radiate. However, the slots are displaced from the either side of the axis in array design. It is possible to produce required polarized fields by making slots suitably inclined. The work on such arrays for the generation of prefixed pattern is not available in the literature. With effect such a work is important in radar applications. In view of these facts, intensive studies are made to design array of displaced slots to produce narrow beams with a specified side lobe levels in the present work. Designed conductances are computed for array pattern and slots are designed to match their conductances with those of desired.

Keywords: Broadwall slot, Conductance,Offset slot parameter, Dissipation power.

## I. Introduction

The directional characteristics like high antenna gain, low side lobes and steerable beams are produced by the arrays of radiating elements. For point to point communication, low side lobes with narrow beamwidth are to be obtained. Without any aerodynamic drag, array antennas scans the beam electronically, thus the array antennas are preferred over horn and reflector antennas. For essential applications, design of waveguide slotted arrays is done to generate far field pattern with low side lobes. Sampling determines the element weights at the junction.

Development of theoretical analysis and design tools is used by the broad-wall slot arrays and is available in open literature. A design procedure is developed in 1978 by Elliot and Kurtz [1] that permits length and slot offset parameter to be determined with the specification of desired pattern and input admittance. Representation of the active admittance in terms of voltage, self and mutual admittance of the slot is presented. A similar design approach is developed for series slot array that are waveguide-fed [2] and broad wall slots that are spaced non-resonantly [3] . An improved version is presented by Robert S. Elliot [4].

Approximation of $\mathrm{TE}_{20}$, internal mutual coupling and its folding into design formulas is indicated by Elliot et al. [5]. Characterization data of isolated slot procedure is used by Elliot, with an assumption that sinusoid represents electric field and shunt element represents the discontinuity in slot of an equivalent transmission line. Effect of finite waveguide wall thickness is neglected in the design of slotted array, though it is incorporated in analysis of isolated slot.

Based on method of least squares (MLS), a new method of optimization and design of standing wave fed and traveling wave fed centered inclined slot arrays of rectangular waveguide with cut in the broad wall is presented by Oraizi et al. [6]. Design of planar slot arrays that are waveguide fed, its analysis and development is presented by Rengarajan et al. [7]. This method achieves specifications of low average side lobe that is used in radiometer applications.

The array antennas are widely used in radar and wireless communications because of their low losses and high power handling capacity with low side lobe levels. M.Mondal and A. Chakrabarty [8] proposed that adjusting the slot offset parameter from the waveguide centre line and by controlling the slot excitation, the desired array pattern will be obtained. Determination of the resonant slot length and the circuit parameter variations with the change in the slot offset parameter is very much important in the array design.
To treat the slots in the broad wall of the rectangular waveguide, the theory enlarges on Stevenson method and based on the babinet's principle, a modified form of Booker's relation is used by Elliot and Kurtz [9]. The module with the slot cut in the broad wall of the rectangular waveguide is a two port device and the origin is taken at the cross section of the waveguide that bisects the slot. Propagation of the waveguide is done only by the dominant $\mathrm{TE}_{01}$ mode.
G.S.N.Raju et al[10] explained that arrays with the slots in the broad wall of the rectangular waveguide generate a beam with strong cross polarization which is a great limitation. This limitation is avoided by using cascading sections at the junctions. Resonance frequency can be reduced to about 9.4 GHz by increasing the slot length.

The initial length and the offset for each slot is selected based on the radiation pattern and input match requirements proposed by J.J. Gulick, R.S. Elliott [11]. After the initial set selection, array analysis is to be performed to determine input match requirements and the actual pattern. To obtain the desired pattern, the
assumption to be considered is that, aperture field magnitude does not alter shape but scales by some constant and its phase will have constant shift but retains the shape.

In the present work, the element conductance is designed by normalizing it with respect to $\mathrm{TE}_{01}$ mode admittance. Formulation developed by R.E. Collin [12] is used to obtain resonant array conductance in the longitudinal slot of the broad wall for the triangular on different pedestal amplitude distribution. The slot offset parameter controls the excitation level of the slot and this characteristic is used to design the slot array.

## II. Amplitude Distributions

To reduce the side lobe level, different amplitude distributions are used like uniform, circular, triangle, raised cosine on pedestal, triangle on pedestal. The simplest is uniform amplitude distribution, as all elements are excited equally.
Two element uniform array radiation pattern is,

$$
\begin{equation*}
E(u)=\cos (k L u) \tag{1}
\end{equation*}
$$

Here, $u=\sin \theta$
$\mathrm{k}=2 \pi / \lambda$
$2 \mathrm{~L}=$ array length
$\lambda=$ operating wavelength
$\mathrm{E}(\mathrm{u})=$ radiation field
The total filed intensity of the radiating isotropic sources $a\left(y_{1}\right), a\left(y_{2}\right), a\left(y_{3}\right)----a\left(y_{N}\right)$ etc... that has different amplitudes and same phase is,
$\mathrm{E}(\mathrm{u})=2\left[\mathrm{a}\left(\mathrm{y}_{1}\right) \cos \mathrm{u}+\mathrm{a}\left(\mathrm{y}_{2}\right) \cos 2 \mathrm{u}+\mathrm{a}\left(\mathrm{y}_{3}\right) \cos 3 \mathrm{u}+---+\mathrm{a}\left(\mathrm{y}_{\mathrm{N}}\right) \cos \mathrm{Nu}\right]$

## III. Radiation Pattern of Tapered Amplitude Distribution

In this paper, triangular on pedestal distribution is considered to reduce the side lobe levels further.
The representation of triangular on pedestal distribution is,

$$
\begin{equation*}
\mathrm{A}\left(\mathrm{x}_{\mathrm{n}}\right)=\left(1-\mathrm{h}\left|\mathrm{x}_{\mathrm{n}}\right|\right), \quad-1 \leq \mathrm{x}_{\mathrm{n}} \leq 1 \tag{3}
\end{equation*}
$$

Where,
$h$ is the pedestal height of $0.5,0.9$
The radiation pattern due to line source is,

$$
\begin{equation*}
E(u)=\int_{-L}^{L} A(x) e^{j \frac{2 \pi L}{\lambda} u x} d x \tag{4}
\end{equation*}
$$

Where, $\mathrm{A}(\mathrm{x})$ is the aperture distribution
The expression for radiation pattern of discrete array is,

$$
\begin{equation*}
\left.\mathrm{E}(\mathrm{u})=\sum_{\mathrm{n}=1}^{\mathrm{N}} \mathrm{~A}\left(\mathrm{x}_{\mathrm{n}}\right) \mathrm{e}^{\mathrm{j}\left[\frac{2 \pi \mathrm{~L}}{\lambda} \mathrm{ux}\right.}+\phi\left(\mathrm{x}_{\mathrm{n}}\right)\right] \tag{5}
\end{equation*}
$$

Here, $\quad u=\sin \theta$
$\theta=$ angle of observer and broadside
$\mathrm{N}=$ Total number of elements
$\mathrm{x}_{\mathrm{n}}=$ Spacing function $=\frac{2 \mathrm{n}-\mathrm{N}-1}{\mathrm{~N}}$
$\phi\left(\mathrm{x}_{\mathrm{n}}\right)=$ Excitation phase ' n ' ' element
$\mathrm{A}\left(\mathrm{x}_{\mathrm{n}}\right)=$ Amplitude distribution of the $\mathrm{n}^{\text {th }}$ element
$2 \pi / \lambda=$ Normalized array length.
The spacing function used in the above expression is suggested by Ishimaru [13].
The triangular on pedestal amplitude distribution and radiation pattern are as shown in the Fig. 1, 2 and 3.

Fig.1: Amplitude distribution of triangular on pedestal height $0.5,0.9$

Fig.2: Radiation pattern of triangular on pedestal height $0.5,0.9$ for $\mathrm{N}=20$

Fig.3: Radiation pattern of triangular on pedestal height $0.5,0.9$ for $\mathrm{N}=40$

## IV. Formulation of Longitudinal Slot Resonant Array:

Resonant array is a broadside array with $\lambda_{\mathrm{g}} / 2$ spacing with slot offsets placed alternatively on the opposite sides of the centre line as shown in Fig. 4.

Fig. 4: Resonant array with longitudinal slots in the broad wall of rectangular waveguide
The assumptions made in the longitudinal slots in the broad wall of rectangular waveguide shown in Fig. 4 are waveguide is infinitely long, propagation of the $\mathrm{TE}_{10}$ mode is allowed by the waveguide in the positive $z$ direction, walls of the waveguide are perfectly conducting, matched load terminates the slot so that no incident wave exists.

The additional scattered modes are present due to the presence of slot in discontinuity region.
Magneto motive force equals the slot current and its expression is,

$$
\begin{equation*}
\mathrm{I}=2 \int \mathbf{H} . \mathrm{ds} \tag{6}
\end{equation*}
$$

The voltage across slot is,

$$
\begin{equation*}
V_{\mathrm{s}}=\int \mathbf{E} . \mathrm{ds} \tag{7}
\end{equation*}
$$

The slot admittance expression is,

$$
\begin{equation*}
Y_{S}=\frac{2 \int \mathrm{H} . \mathrm{ds}}{\int \mathrm{E} . \mathrm{ds}} \tag{8}
\end{equation*}
$$

Relation between slot admittance that radiates into half space and the impedance of the complimentary dipole $\left(Z_{D}\right)$ is as follows [14]:

$$
\begin{equation*}
\mathrm{Y}_{\mathrm{s}}=\frac{2}{\mathrm{n}^{2}} \mathrm{Z}_{\mathrm{D}} \tag{9}
\end{equation*}
$$

The field equations for the regions $\mathrm{z} \leq \mathrm{z}_{1}$ are:

$$
\begin{align*}
& \mathbf{E}=\mathrm{A}_{10} \mathbf{E}_{10}^{\mathrm{e}+}+\Gamma \mathrm{A}_{10} \mathbf{E}_{10}^{\mathrm{e}-}+\sum_{\mathrm{p}}^{1} \mathrm{C}_{\mathrm{p}} \mathbf{E}_{\mathrm{p}}^{-} \\
& \mathbf{H}=\mathrm{A}_{10} \mathbf{H}_{10}^{\mathrm{e}+}+\Gamma \mathrm{A}_{10} \mathbf{H}_{10}^{\mathrm{e}-}+\sum_{\mathrm{p}}^{1} \mathrm{C}_{\mathrm{p}} \mathbf{H}_{\mathrm{p}}^{-} \tag{10}
\end{align*}
$$

Where, $\mathrm{A}_{10}$ is the incident mode amplitude
$I$ is the reflection coefficient for $\mathrm{TE}_{10}$ mode
$\mathrm{C}_{\mathrm{p}}$ is mode amplitude that is backward scattered
The field equations for the regions $\mathrm{z} \geq \mathrm{z}_{2}$ are:

$$
\begin{align*}
& \mathbf{E}=\mathrm{TA}_{10} \mathbf{E}_{10}^{\mathrm{e}+}+\sum_{\mathrm{p}}^{1} \mathrm{D}_{\mathrm{p}} \mathbf{E}_{\mathrm{p}}^{+} \\
& \mathbf{H}=\mathrm{TA}_{10} \mathbf{H}_{10}^{\mathrm{e}+}+\sum_{\mathrm{p}}^{1} \mathrm{D}_{\mathrm{p}} \mathbf{H}_{\mathrm{p}}^{+} \tag{11}
\end{align*}
$$

Where, T is the transmission coefficient for $\mathrm{TE}_{10}$ mode
$D_{p}$ is the mode amplitude that is forward scattered
The considered regions $\mathrm{z} \leq \mathrm{z}_{1}$ and $\mathrm{z} \geq \mathrm{z}_{2}$ are related by means of reciprocity theorem.

$$
\begin{equation*}
\oint\left[\mathbf{E} \times \mathbf{H}_{\mathrm{p}}^{+} . \hat{\mathrm{nds}}-\mathbf{E}_{\mathrm{p}}^{+} \times \mathbf{H} . \hat{\mathrm{n}} \mathrm{ds}\right]=0 \tag{12}
\end{equation*}
$$

Where, $\hat{\mathrm{n}}$ is the unit outward normal vector.
Using normalization of modes and the power orthogonality, equation (12) yields,

$$
\begin{align*}
& \mathrm{C}_{\mathrm{p}}=\frac{1}{2} \oint_{\mathrm{s}}\left(-\mathrm{a}_{\mathrm{x}}\right) \mathrm{E}_{\mathrm{s}}(\mathrm{z}) \mathbf{H}_{\mathrm{p}}^{+} \mathrm{d} \mathrm{~s}  \tag{13}\\
& \mathrm{D}_{\mathrm{p}}=\frac{1}{2} \oint_{\mathrm{s}}\left(-\mathrm{a}_{\mathrm{x}}\right) \mathrm{E}_{\mathrm{s}}(\mathrm{z}) \mathbf{H}_{\mathrm{p}}^{-} \mathrm{ds} \tag{14}
\end{align*}
$$

The modes that have tangential magnetic fields along the slot are excited. In the broad wall only TE modes are excited. If $C_{p}=D_{p}$, the longitudinal slot becomes a shunt element.

The normalized field component is [18],

$$
\begin{equation*}
h_{z}^{\mathrm{e}}=\frac{\mathrm{j} \pi}{\sqrt{\mathrm{k}_{0} \beta_{10} \mathrm{\eta b}^{3} \mathrm{a} / 2}} \tag{15}
\end{equation*}
$$

For a slot of length 2 L and width w , using the equation (15) for dominant $\mathrm{TE}_{10}$ mode in equation (13) yields,

$$
\begin{equation*}
\mathrm{C}_{10}=-\frac{\mathrm{j} \pi}{\sqrt{2 \mathrm{~b}^{3} \mathrm{ak}_{0} \beta_{10} \eta}} \cos \left(\frac{\pi \mathrm{x}_{0}}{\mathrm{~b}}\right) \int_{-\mathrm{L}}^{\mathrm{L}} \mathrm{wE} \mathrm{E}_{\mathrm{s}}(\mathrm{z}) \mathrm{e}^{-\mathrm{j} \beta_{10} \mathrm{z} \mathrm{dz}} \tag{16}
\end{equation*}
$$

Similarly,

$$
\begin{equation*}
D_{10}=-\frac{j \pi}{\sqrt{2 b^{3} \mathrm{ak}_{0} \beta_{10} \eta}} \cos \left(\frac{\pi \mathrm{x}_{0}}{\mathrm{~b}}\right) \int_{-\mathrm{L}}^{\mathrm{L}} \mathrm{wE}_{\mathrm{s}}(\mathrm{z}) \mathrm{e}^{+\mathrm{j} \beta_{10} \mathrm{z}} \mathrm{dz} \tag{17}
\end{equation*}
$$

Where,
$\mathrm{C}_{10}$ is the dominant mode amplitude that is backward scattered
$\mathrm{D}_{10}$ is the dominant mode amplitude that is forward scattered
The voltage across the slot of half wavelength long due to incident $\mathrm{TE}_{10}$ mode is,

$$
\begin{equation*}
\mathrm{V}(\mathrm{z})=\mathrm{V}_{\mathrm{m}} \sin [\mathrm{k}(\mathrm{~L}-|\mathrm{z}|)] \tag{18}
\end{equation*}
$$

Thus, the equations (16) and (17) are simplified as:

$$
\begin{equation*}
\mathrm{C}_{10}=\mathrm{D}_{10}=\frac{-\mathrm{j} \mathrm{v}_{\mathrm{m}}}{\pi} \sqrt{\frac{2 \mathrm{~b} \mathrm{k}_{0}}{\mathrm{an} \beta_{10}}} \cos \left(\frac{\pi \mathrm{x}_{0}}{\mathrm{~b}}\right)\left(\cos \beta_{10} \mathrm{~L}-\operatorname{cosk}_{0} \mathrm{~L}\right) \tag{19}
\end{equation*}
$$

The reflection coefficient $\Gamma$ is,

$$
\begin{aligned}
& \Gamma=\frac{\mathrm{C}_{10}}{\mathrm{~A}_{10}} \\
& \Gamma=\frac{-\mathrm{j} \mathrm{~V}_{\mathrm{m}}}{\mathrm{~A}_{10} \pi} \mathrm{k} \\
& \text { Where, } \mathrm{k}=\sqrt{\frac{2 \mathrm{bk}_{0}}{\mathrm{an} \beta_{10}}} \cos \left(\frac{\pi \mathrm{x}_{0}}{\mathrm{~b}}\right)\left(\cos \beta_{10} \mathrm{~L}-\operatorname{cosk}_{0} \mathrm{~L}\right)
\end{aligned}
$$

The transmission coefficient is,

$$
\begin{equation*}
\mathrm{T}=1+\frac{\mathrm{D}_{10}}{\mathrm{~A}_{10}}=1+\frac{\mathrm{C}_{10}}{\mathrm{~A}_{10}}=1+\mathrm{I} \tag{21}
\end{equation*}
$$

The energy balance equation is defined as,
Power radiated=Incident power-Reflected power-transmitted power

$$
\begin{equation*}
\left|V_{\mathrm{m}}\right|^{2} Y_{\mathrm{S}}=\left|\mathrm{A}_{10}^{2}\right|\left(1-|\Gamma|^{2}-|T|^{2}\right) \tag{22}
\end{equation*}
$$

Thus, the normalized admittance of the shunt element is,

$$
\begin{equation*}
\frac{Y_{\text {in }}}{Y_{10}}=\frac{4 \mathrm{k}^{2}}{\mathrm{Y}_{\mathrm{s}}} \tag{23}
\end{equation*}
$$

Substitute the value of k and $\mathrm{Y}_{\mathrm{s}}$ in equation (23).

$$
\begin{align*}
& \frac{\mathrm{Y}_{\text {in }}}{\mathrm{Y}_{10}}=\frac{2 \eta^{2}}{\mathrm{Z}_{\mathrm{D}}}\left(\sqrt{\left.\frac{2 \mathrm{bk} \mathrm{k}_{0}}{\mathrm{a} \mathrm{\eta} \mathrm{\beta}_{10}} \cos \left(\frac{\pi \mathrm{x}_{0}}{\mathrm{~b}}\right)\left(\cos \beta_{10} \mathrm{~L}-\operatorname{cosk}_{0} \mathrm{~L}\right)\right)^{2}}\right. \\
& \frac{\mathrm{Y}_{\text {in }}}{\mathrm{Y}_{10}}=\frac{4 \eta \mathrm{~b} \mathrm{k}_{0}}{\mathrm{Z}_{\mathrm{D}} \beta_{10}} \cos ^{2}\left(\frac{\pi x_{0}}{\mathrm{~b}}\right)\left(\cos \beta_{10} \mathrm{~L}-\operatorname{cosk}_{0} \mathrm{~L}\right)^{2} \tag{24}
\end{align*}
$$

For a half wave thin dipole, the value of $Z_{D}$ is 73.13 .
Substitute the value $\mathrm{Z}_{\mathrm{D}}, \mathrm{k}=\lambda_{0} / 2$ and shift the origin as $\mathrm{x}_{1}=\mathrm{x}_{0}-\frac{\mathrm{a}}{2}$ in equation (23) and the equation gets modified as,

$$
\begin{equation*}
\frac{\mathrm{Y}_{\mathrm{in}}}{\mathrm{Y}_{0}}=2.09 \frac{\mathrm{~b}}{\mathrm{a}} \frac{\mathrm{k}_{0}}{\beta_{10}} \cos ^{2}\left(\frac{\pi \beta_{10}}{2 \mathrm{k}_{0}}\right) \sin ^{2}\left(\frac{\pi \mathrm{x}_{1}}{\mathrm{~b}}\right) \tag{25}
\end{equation*}
$$

The normalized conductance of the resonant longitudinal slot with an offset parameter $\mathrm{x}_{1}$ is,

$$
\begin{equation*}
\mathrm{g}_{\mathrm{i}}=2.09 \frac{\mathrm{~b}}{\mathrm{a}} \frac{\lambda_{\mathrm{g}}}{\lambda_{0}} \cos ^{2}\left(\frac{\pi \lambda_{0}}{2 \lambda_{\mathrm{g}}}\right) \sin ^{2}\left(\frac{\pi \mathrm{x}_{1}}{\mathrm{~b}}\right) \tag{26}
\end{equation*}
$$

Where,
a is the narrow wall dimension of rectangular waveguide
$b$ is the broad wall dimension of rectangular waveguide
$\lambda_{\mathrm{g}}$ is the guided wavelength
$\lambda_{0}$ is the free space wavelength.
The equivalent circuit of the waveguide and slot is connected as a shunt element across a transmission line with unit characteristic impedance, conductance $\mathrm{g}_{\mathrm{i}}$ and has a propagation phase constant $\beta$.
By offsetting every other slot on opposite sides from the centre line, an additional phase of $\pi$ is introduced, due to $\lambda_{\mathrm{g}} / 2$ spacing all slots excited in phase. The equivalent circuit of array consists of I conductance's connected across a transmission line with $\lambda_{\mathrm{g}} / 2$ spacing is shown in Fig. 5.

Fig. 5: Equivalent circuit of array of slots in broad wall
It is possible to evaluate the required conductance's of the slots in the array following the method proposed by G. A. Yevastropov and Tsarapkin [19]. This method takes care of internal reflections into account. For the sake of conductances the method is briefly given below. The power delivered to junctions is given by $\mathrm{P}_{\mathrm{i}}$ and $\mathrm{P}_{\mathrm{d}}$ represents power dissipated in the matched load.
According to the power balanced condition,

$$
\begin{equation*}
\sum_{\mathrm{i}=1}^{\mathrm{I}} \mathrm{P}_{\mathrm{i}}+\mathrm{P}_{\mathrm{d}}=1 \tag{27}
\end{equation*}
$$

When the feed guide is matched terminated $\mathrm{R}_{\mathrm{I}}=0$. In such cases the amplitude of incident wave into the matched load is used as a reference.
If $I_{I}$ is incident voltage, we have,

$$
\begin{equation*}
P_{d}=I_{I}^{2} .1 \tag{28}
\end{equation*}
$$

Hence, the normalized conductance presented by $\mathrm{I}^{\text {th }}$ junction is,

$$
\begin{equation*}
\mathrm{g}_{\mathrm{I}}=\frac{\mathrm{P}_{\mathrm{I}}}{\mathrm{I}_{\mathrm{I}}^{2}}=\frac{\mathrm{P}_{\mathrm{I}}}{\mathrm{P}_{\mathrm{d}}} \tag{29}
\end{equation*}
$$

The conductance of $\mathrm{I}-1^{\text {th }}$ junction is,

$$
\begin{equation*}
\mathrm{g}_{\mathrm{I}-1}=\frac{\mathrm{P}_{\mathrm{I}-1}}{\left|\mathrm{I}_{\mathrm{I}-1}+\mathrm{R}_{\mathrm{I}-1}\right|^{2}} \tag{30}
\end{equation*}
$$

Using a recursive set of relations, the expression for the slot conductance is,

$$
\begin{equation*}
\mathrm{g}_{\mathrm{I}}=\frac{\mathrm{P}_{\mathrm{I}}}{\sum_{\mathrm{q}=1}^{\mathrm{I}} \mathrm{P}_{\mathrm{q}}} \frac{1-\mathrm{P}_{\mathrm{d}}}{\mathrm{P}_{\mathrm{d}}} \tag{31}
\end{equation*}
$$

## V. Results

Using equation (31) the required conductance of each slot in the array are evaluated for $\mathrm{P}_{\mathrm{d}}=0.1,0.15$. Computations are made for small and large arrays. The results are presented in Tables 1 to 8 .
In order to design the corresponding slots in the array, the realized conductances are computed by different slot displacements $x_{1}=3 \mathrm{~mm}, 4 \mathrm{~mm}$. The realized conductances by using the equation (26) are also presented in the same tables. This method can be extended to any type of arrays.

Table 1: Number of elements $=20, \mathrm{~h}=0.5, \mathrm{x}_{1}=4 \mathrm{~mm}$, Table 2: Number of elements $=20, \mathrm{~h}=0.5, \mathrm{x}_{1}=4 \mathrm{~mm}, \mathrm{Pd}=0.15$ $\mathrm{Pd}=0.1$

## VI. Conclusions

It is evident from the results that the slot array in the broad wall of a rectangular waveguide is successfully designed. It has been possible to bring out realized conductances closed to desired ones. The same used for small and large arrays. The desired radiation pattern is specified very clearly and it is generated using distribution represented by triangle on pedestals and the side lobe levels controlled by the inherent taper itself. The array design has become simple because the characteristics are controlled by $\mathrm{x}_{1}$ by keeping other parameters constant.
