Abstract: This paper deals with the closed loop control of the three switch interleaved Forward Converter with motor load. When any step change occurs at the input of the open loop three switch interleaved forward converter, the output is also disturbed. In order to avoid this, a closed looped control is introduced. By using the closed loop control, the steady state error in speed is reduced. The DC input is converted into high frequency AC using the Forward Converter. The high frequency AC is rectified using a Half-wave rectifier and the output voltage is regulated using the closed loop system. The results of closed loop system are compared with the open loop system.

Keywords: Interleaved Forward Converter, DC-DC Converter, Matlab, Simulation, Microcontroller.

I. Introduction

Many industrial applications require DC power. A DC to DC converter is an Electronic Converter which converts a source of Direct Current (DC) from one voltage level to another. DC to DC converters (with isolation) convert one DC voltage level to another, by storing the input energy temporarily and then releasing that energy to the output at a different voltage level. The energy can be stored in magnetic field storage components (inductors, transformers) or electric field storage components (capacitors). This conversion method is more efficient than linear voltage regulation which dissipates unwanted power as heat. The efficiency is increased by the use of power FETs, which operate at high frequency than power bipolar transistors. DC to DC converters are important in portable electronic devices such as cellular phones and computer which are supplied with power from batteries.

Galvanic isolation is the principle of isolating functional sections of electrical system by preventing the moving of charge carrying particles from one section to another, i.e. there is electric current flowing directly from one section to the next. Energy and/or information can still be exchanged between the sections by other means e.g. capacitance, inductance electromagnetic waves, optical, acoustic or mechanical means. Such a principle is used in these DC to DC converters (with isolation). Two types of converter with galvanic isolation are Flyback converter and Forward converter. Forward converter is a popular switched mode power supply (SMPS) circuit that is used for producing isolated and controlled DC voltage from the unregulated DC input supply. Applications of this forward converters are Power supply for DC motor, Battery charging, Battery operated Electric vehicle, Telecom applications etc.

The input DC supply for a forward converter is often derived after rectifying (and little filtering) the AC voltage. The forward converter, when compared with the flyback circuit is generally more energy efficient and is used for high power output applications (in the range of 100 watts to 200 watts). Whereas, the flyback converter used for low power application below is 100 watts. The forward converter is simple and retains many features of the buck converter. With a proper choice of the transformer turns ratio, the forward Converter can attain wide step down voltage which is useful for offline applications. Moreover, this forward converter is quite easy to control. These advantages make the forward converter for low to medium isolated offline power applications.

The above literature does not deal with simulink modeling of closed loop controlled three switch interleaved forward converter with motor load. Three switch interleaved forward converter is proposed for the control of DC motor. This paper deals with the modeling and the simulation of the closed loop controlled three switch interleaved forward converter with motor load.

II. Forward Converter

The block diagram of forward converter system is shown in Fig 1. This converter converts unregulated DC power to regulated DC power. It contains high frequency transformer which is also called isolation transformer. This transformer provides isolation between the load and the main circuit. As the frequency increases, the size of the transformer decreases. This is because the flux decreases with the increase in the frequency of the transformer.

III. Simulation Results

The simulink model for three switch DC-DC converter is shown in Fig 2.1. The scopes are connected to measure output voltage and output current. A step change in the input voltage is applied to the open loop system.

3.1 OPEN LOOP CONTROLLED THREE SWITCH FORWARD CONVERTER WITH MOTOR LOAD

The open loop controlled three switch forward converter with motor load is shown in Fig 2.1.

![Fig 2.1 Open loop controlled three switch forward converter with motor load](image2)
DC input voltage is shown in Fig 2.2 and it is 300 volts. When a step change is applied at $t=0.3$ seconds, the input voltage increases to 314V.

![Fig 2.2 Input voltage](image)

The speed and torque are shown in Figs 2.3 and 2.4 respectively. The rise in torque is due to the step rise in the input voltage.

![Fig 2.4 Torque](image)

3.2 THREE SWITCH FORWARD CONVERTER SYSTEM WITH CLOSED LOOP CONTROL

The three switch serial input interleaved forward converter with closed loop is shown in Fig 3.1. The PI controller is used to reduce the error in the output. The output voltage is measured and it is compared with the reference voltage. The error is processed by a PI controller. The output of the PI controller is the input to the comparator. The diodes in the rectifier are replaced by the MOSFETs so that the output voltage can be controlled. The output voltage is regulated by controlling the pulse width applied to the MOSFETs. The value of $K_p$ and $K_i$ are obtained using Zigler Nicolos method. $K_p$ and $K_i$ are as follows: $K_p=2, K_i=0.016$. 

DOI: 10.9790/1676-1206037175
DC input voltage is shown in Fig 3.2 and its value is 324 volts.

The speed and torque responses are shown in Figs 3.3 and 3.4 respectively. It can be seen that the torque reaches steady state value due to the action of closed loop system. The motor runs at a speed equal to the set value. The torque settles at 3 N-m.
IV. Conclusion

Open loop and closed loop controlled three switch serial input interleaved forward converter fed DC drive systems are modeled and simulated using the MATLAB Simulink and the results are presented. The speed of the three switch converter fed DC drive system is regulated using PI controller. The steady state error is reduced by using closed loop system. The simulation results are in line with the predictions. The disadvantage of three switch forward converter is that it requires three switches and three drivers.

The scope of this work is the modeling and simulation of closed loop controlled three switch ILFC with motor load. The hardware will be implemented in future.
