A deteriorating inventory model for quadratic demand and constant holding cost with partial backlogging and inflation

Dr. Ravish Kumar Yadav, Amit Kumar Vats

(Associate Professor, Department of Mathematics, Hindu college, Moradabad)

(Department of Applied Science ABES Group of Institutions Ghaziabad)

Abstract: In most of the deteriorating items inventory model, demand rate has considered as a constant function. But in realistic situations, these costs vary according to time. So, in this paper, we developed a deterministic deteriorating inventory model with inflation in which demand rate is non-linear and partial backlogging rate is variable and depend on the length of the next replenishment. Shortages are allowed and partially backlogged. The model is solved numerically by minimizing the total cost over a cycle.

Keywords: inventory, deteriorating items, shortages, time dependent demand, partial backlogging, constant holding cost and inflation.

I. Introduction

Buzacott (1975) developed the first EOQ model taking inflationary effects into account. In this model, a uniform inflation is assumed for all the associated costs and an expression for the EOQ is derived by minimizing the average annual cost. At most the same time Misra (1975) developed an economic order quantity model taking inflationary effects on inventory systems into account. In this model, a uniform inflation rate for all the costs is assumed and an expression for the EOQ is derived by minimizing the average annual cost. Misra (1979) then extended the EOQ model with different inflation rates for various associated costs. Today, inflation has become a permanent and integral part of the economy. Many researchers have shown the inflationary effect on inventory policy. Chang (2004) study EOQ model with deteriorating items under inflation when supplier credits linked to order quantity. Misra (1979) given a note on optimal inventory management under inflation. Yang (2004) work on inventory models for deteriorating items with shortages under inflation. Yang (2006) given Two-warehouse partial backlogging inventory models for deteriorating items under inflation

Deterioration is a term now commonly used in health care, to describe worsening of a patient's condition. It is often used as a shortened form of 'deterioration not recognized or not acted upon'. Much work to reduce harm from deterioration has been undertaken by the National Patient Safety Agency. It is the process in which an item loses its utility and becomes useless. Inventory in deteriorating items is a general phenomenon in daily life. The items like milk, fruit, vegetables, fashion goods, electronic components, eggs, medicines, wine and gasoline etc. are called deteriorating items. So deterioration of physical goods in stock is a very realistic factor and there is a big need to consider this in inventory model.

Harris (1915) developed first inventory model, Economic Order Quantity, which has generalized by Wilson (1934) and he gave a formula to obtain economic order quantity. Inventory of deteriorating items first studied by Whit-in (1957), he considered the deterioration of fashion goods at the end of prescribed storage period. Ghare and Schrader (1963) extended the classical EOQ formula with exponential decay of inventory due to deterioration and gave a mathematical model of inventory of deteriorating items. Dave and Patel (1981) developed the first deteriorating inventory model with linear trend in demand. He considered demand as a linear function of time. Chang and Dye (1999) developed an inventory model with time varying demand and partial backlogging. Goyal and Giri (2001) gave recent trends of modeling in deteriorating items inventory. They classified inventory models on the basis of demand variations and various other conditions or constraints. Ouyang et al. (2005) developed an inventory model for deteriorating items with exponential declining demand and partial backlogging. Dye et al. (2007) Find an optimal selling price and lot size with a varying rate of deterioration and exponential partial backlogging. They assume that a fraction of customers who backlog their orders increases exponentially as the waiting time for the next replenishment decreases. Alamri and Balkhi (2007) studied the effects of learning and forgetting on the optimal production lot size for deteriorating items with time varying demand and deterioration rates. Dye (2007) gave an inventory model to determining optimal selling price and lot size with a varying rate of deterioration and exponential partial backlogging and deterministic inventory model for deteriorating items with capacity constraint and time-proportional backlogging rate. Teng et al. (2007) gave a comparison between two pricing and lot sizing models with partial backlogging and deteriorated items. Roy (2008) developed an inventory model for deteriorating items with time varying holding cost and demand is price dependent. Liao (2008) aver an EOQ model with non

In this paper, we developed a deterministic deteriorating inventory model with inflation in which demand rate are quadratic function of time, deterioration rate is constant, backlogging rate is variable and depend on the length of the next replenishment, shortages are allowed and partially backlogged. The model is solved numerically by minimizing the total inventory cost for cycle.

II. Notation and Assumptions

The mathematical model is based on the following notations and assumptions. Following notation are used in paper.

- \( C_o \): the ordering cost per order;
- \( C_p \): the purchase cost per unit;
- \( \theta \): the deterioration rate;
- \( C_{H}(t) \): the inventory holding cost per unit per time unit;
- \( C_B \): the backordered cost per unit short per time unit;
- \( C_L \): the cost of lost sales per unit;
- \( t_1 \): the time at which the inventory level reaches zero \( t_1 \geq 0 \);
- \( t_2 \): the length of period during which shortages are allowed, \( t_2 \geq 0 \);
- \( T \): the length of cycle time;
- \( I_{\text{max}} \): the maximum inventory level during \([0, T]\);
- \( IB_{\text{max}} \): the maximum inventory level during shortage period;
- \( Q_o \): \((I_{\text{max}}+ IB_{\text{max}})\) the order quantity during a cycle of length \( T \);
- \( I_p(t) \): the positive inventory level at time \( t \);
- \( I_n(t) \): the negative inventory level at time \( t \);
- \( T_C(t_1, t_2) \): the total cost per time unit.

Assumptions

The model is based on the following assumptions

1. The demand rate is time dependent that is if ‘\( a \)’ is fixed fraction of demand and ‘\( b \)’ and ‘\( c \)’ are that fraction of demand which is vary with time then demand function is \( D(t) = a + bt + ct^2 \), where \( a > 0, b > 0, c > 0 \).
2. The inflation rate is \( r(t) = \text{e}^{-rt} \) where \( r > 0 \).
3. Holding cost is constant \( h(t) = h \).
4. Shortages are allowed and partially backlogged.
5. The lead time is zero.
6. The replenishment rate is infinite.
7. The planning horizon is finite.
8. The deterioration rate is constant.
9. During stock out period, the backlogging rate is variable and dependent on the length of the waiting time for next replenishment. So that the backlogging rate for negative inventory is, \( R_B(t) = \frac{1}{1+\delta(t-t')} \) where \( \delta \) is backlogging parameter and \((T-t)\) waiting time (\( t_1 \leq t \leq t_2 \)).

III. Mathematical Formulation of Model

The rate of change of inventory during positive stock period \([0, t_1]\) and shortage period \([t_1, T]\) is governed by the differential equations.

\[
\frac{dI_p}{dt} + \theta I_p = -(a + bt + ct^2), \quad 0 < t \leq t_1 \quad (1)
\]
A deteriorating inventory model for quadratic demand and constant holding cost with……

\[
\frac{d I_N}{dt} = -\frac{-1}{1+\delta(T-t)}(a + bt + ct^2), \ t_1 \leq t \leq T \quad \ldots (2)
\]

With boundary conditions \( I_P(t) = I_N(t) = 0 \) at \( t = t_1 \) and \( I_N(t) = I_{\text{max}} \) at \( t = 0 \). \ldots (3)

IV. Analytical Solution

Case.1. The inventory level have not shortages:

In this period \([0, t_1]\), the inventory depletes due to the deterioration and demand. So the inventory level at the time during \([0, t_1]\) form the differential equation:

\[
\frac{d I_P}{dt} + \theta I_P = -(a + bt + ct^2), \ 0 < t \leq t_1
\]

With boundary conditions \( I_P(t) = 0 \) at \( t = t_1 \).

The system gives the solution:

\[
I_P(t) = \frac{a}{\theta} + \frac{b(\theta t_1 - 1)}{\theta^2} + \frac{c(\theta t_1 - 1)^2}{\theta^3} - \frac{1}{\theta} \text{log} \left( \frac{1+\delta(T-t)}{1+\delta(T-t_1)} \right)
\]

where \( 0 < t \leq t_1 \). …(4)

Case.2. The inventory level having shortage:

In this period \([t_1, T]\), the inventory level depends on demand and a fraction of demand is backlogged. The state of inventory during \([t_1, T]\) form the differential equation:

\[
\frac{d I_N}{dt} + \theta I_N = \frac{-1}{1+\delta(T-t)}(a + bt + ct^2), \ t_1 \leq t \leq T, (T = t_1 + t_2);
\]

With boundary conditions \( I_N(t) = 0 \) at \( t = t_1 \).

The solution of this system:

\[
I_N = \frac{a}{\theta} + \frac{b}{\theta^2} \text{log} \left( \frac{1+\delta(T-t)}{1+\delta(T-t_1)} \right) + \frac{1}{\delta} \left( b + 2c + 2T \right) \left( t - t_1 \right) + \frac{c}{\delta} \left( t - t_1 \right) \left( \delta t + \frac{t_1}{t_1 - 1} \right) - \frac{2\delta - 2}{t_1 - 1}
\]

…(6)

Inventory holding cost

\[
IC_{\text{IH}}(t) = \int_{t_1}^{t} h(t) e^{-rt} I_P(t) \, dt
\]

\[
= \int_{t_1}^{t} \left( \frac{a}{\theta} + \frac{b(\theta t_1 - 1)}{\theta^2} + \frac{c(\theta t_1 - 1)^2}{\theta^3} - \frac{1}{\theta} \text{log} \left( \frac{1+\delta(T-t)}{1+\delta(T-t_1)} \right) - \frac{1}{\theta} \text{log} \left( \frac{1+\delta(T-t_1 - 1)\left( \delta (t + t_1) - 2\delta - 2 \right)}{1+\delta(T-t_1)} \right) \right) e^{-rt} \, dt
\]

…(7)

Backordered cost

\[
C_B = \int_{t_1}^{T} (-I_N) e^{-rt} \, dt
\]
A deteriorating inventory model for quadratic demand and constant holding cost with……

\[ C_a = \int_0^T \frac{1}{\delta} [a + bT + cT^2 + \frac{b}{\delta} + \frac{c}{\delta} + \frac{2T}{\delta}] \log \left( \frac{1 + \delta(T - t_1)}{1 + \delta(T - t_1)} \right) e^{-rt} + \frac{1}{\delta} [b + 2c + 2T] (t - t_1) e^{-rt} + \frac{c}{\delta} [(T - t_1) \delta(t + t_1 - 2) e^{-rt} - \frac{1}{2\delta} \delta(t + t_1 - 2) e^{-rt}] dt \]

\[ = \frac{1}{\delta^2} \left( \frac{1}{1 + \delta(T - t_1)} \right) \left( 1 + 2\delta(T - t_1) \right) \left( \log(1 + \delta(T - t_1)) \right) + \frac{1}{2\delta} [b + 2c + 2T] (T - t_1)^2 + \frac{c}{\delta} \left( \frac{1}{1 + \delta(T - t_1)} \right) \left( 1 - \frac{C}{\delta} \right) \left( \frac{1}{1 + \delta(T - t_1)} \right) \left( \log(1 + \delta(T - t_1)) \right) \]

\[ Lost sales cost \]

\[ C_L = \int_{t_1}^T \left[ a e^{-rt} + \frac{1}{1 + \delta(T - t_1)} \right] (a + bt + ct^2) e^{-rt} dt \]

\[ = \int_{t_1}^T \left[ a \left( T - t_1 \right) - \frac{1}{2} \left( 1 + \delta(T - t_1) \right) \left( \log(1 + \delta(T - t_1)) \right) + \frac{1}{2} \left( T - t_1 \right) \right] e^{-rt} dt \]

\[ = \frac{a}{\delta} \left( T - t_1 \right) - \frac{1}{2} \left( T - t_1 \right) \left( \log(1 + \delta(T - t_1)) \right) + \frac{r \left( \frac{1}{2} \left( t_1 \right)^2 \right) + \frac{1}{2} \left( T - t_1 \right) \left( \log(1 + \delta(T - t_1)) \right) \]
A deteriorating inventory model for quadratic demand and constant holding cost with inflation.

\[ + \frac{1}{\delta} \left( (a + bT + cT^2 + \frac{b}{\delta} + \frac{c}{\delta} + \frac{2T}{\delta}) \log[1 + \delta(T - t_1)] - (b + 2c + 2T(T - t_1)) - c(T - t_1) \delta(T - t_1) + 2) \right), \]

... (13)

Ordering cost \( C_0 = A \).

**Total Cost**

Therefore the total cost per time unit is given by

\[ T_C(t_1, T) = \frac{1}{T} \left[ \text{Ordering cost} + \text{carrying cost} + \text{backordering cost} + \text{lost sale cost} + \text{purchase cost} \right], \]

\[ = \frac{1}{T} \left[ C_0 + IC_H + C_0 + C_L + PC \right]. \]

\[ T_C(t_1, T) = \frac{1}{T} \left[ \left( \frac{a}{\theta} + \frac{b(\theta t_1 - 1)}{\theta^2} + \frac{c(\theta t_1 - 1)^2}{\theta^3} \right) \left( \frac{1 - e^{-rt_1}}{r} \right) - \left( \frac{a}{\theta} \right) \left( \frac{1 - e^{-rt_1}}{r} \right) \right] \]

\[ + \frac{b}{\theta^2} \left( (\theta t_1 - 1) - \frac{1}{\theta} \right) e^{-rt_1} - \frac{c}{\theta^3} \left( \frac{1}{\theta} \right) e^{-rt_1} \]

\[ - \left( (t_1 - 2)^2 + 1 \right) \frac{e^{-rt_1}}{r} - \frac{b}{\theta^2} \left( (t_1 - 2)^2 + \frac{2T}{\theta} + \frac{2T}{\theta^2} \right) \]

\[ + \frac{1}{\delta^2} \left( \frac{a}{\theta} + bT + cT^2 + \frac{b}{\theta} + \frac{c}{\theta} + \frac{2T}{\theta} \right) \left( \log[1 + \delta(T - t_1)] \right) \]

\[ = \frac{1}{2\delta} \left[ b + 2c + 2T(T - t_1)^2 \right] + \frac{c}{6} \left( (T - t_1)^3 - \frac{T}{2} + \frac{2T}{3} \right) \]

\[ + \frac{1}{\delta^2} \left( \frac{a}{\theta} + bT + cT^2 + \frac{b}{\theta} + \frac{c}{\theta} + \frac{2T}{\theta} \right) \left( \log[1 + \delta(T - t_1)] \right) - \frac{r}{6\delta} \left( b + 2c + 2T \right) \left( t_1^3 - T^3 + 3T^2t_1 - 2T^3 \right) \]

\[ \text{where } \theta = \frac{b}{\delta}, \text{ and } \frac{2T}{\delta} \text{ are the parameters of the deterioration process.} \]

The necessary condition for the total cost per time unit to be minimize is

\[ \frac{\partial T_C}{\partial t_1} = 0 \text{ and } \frac{\partial T_C}{\partial T} = 0. \]

**4. Algorithm**

To find out the solution following algorithm used

Step 1 Find derivative \( \frac{\partial T_C}{\partial t_1} = 0, \frac{\partial T_C}{\partial T} = 0 \)

Step 2 Solve (15) for \( t_1 \) and \( t_2 \) where \( T = t_1 + t_2 \)

Step 3 Find total cost from equation (14)

**V. Conclusion**

In this paper, we developed a model for deteriorating item with inflation, quadratic demand and partial backlogging and give analytical solution of the model that minimize the total inventory cost. The deterioration
factor taken into consideration in the present model, as almost all items undergo either direct spoilage or physical decay in the course time, deterioration is natural feature in the inventory system. The model is very practical for the industries in which the demand rate is depending upon the time and holding cost is constant with inflation. This model can further be extended by taking more realistic assumptions such as finite replenishment rate, probabilistic demand rate, variable deterioration rate etc.

VI. Numerical Solution

Consider an inventory system with the following parameter in proper unit $\Lambda = 2500$, $h = 0.5$, $C = 4$, $C_0= 12$, $C_1 = 15$, $\delta = 8$, $a = 25$, $b = 40$, $c = 40$, $\theta = 0.005$ and parameter $r=0.005$. The computer out put of the program by using maple mathematical software is $t_1 = 4.12$, $t_2 = 0.03$ and $TC = 1179$. i.e. the value of $t_1$ at which the inventory level become zero is 4.12 unit and shortage period is 0.03 unit. The effect of changes in the parameter of the inventory model also can be study.
