General Efficiency

Vasile Postolică,
Romanian Academy of Scientists, Vasile Alecsandri University of Bacău, Faculty of Sciences, Department of Mathematics, Informatics and Educational Sciences Romania,

Abstract: This research work is devoted to the general Efficiency presented in the best appropriate environment of the infinite dimensional Ordered Vector Spaces, following our recent results, especially using the largest class of the Convex Cones discovered till now in separated Locally Convex Spaces, named by us Isac’s Cones, and ensuring the existence together with important properties for the efficient points under completeness instead of compactness. New links between the General Efficiency, the Vector (Strong) Optimization and the Choquet Boundaries are given. In this way, the Efficiency is strongly related to the general Optimization, the Potential Theory and conversely, with projections in new fields of research: Theory and Applications of the Generalized Dynamical Systems, Fixed point Theory, the Best Approximation Theory, the study of the Conically Bounded Sets, the study of the nuclearity for the Topological Vector Spaces and so on.

Mathematics Subject Classification 2010 : Primary: 90C48; Secondary: 90B50, 90B70.

Keywords: ordered vector space, general efficiency, multifunction, Pareto optimality, locally convex space, Isac’s (nuclear, supernormal) cone, Choquet boundary, best approximation, splines in H-locally convex spaces.

I. Introduction

Until now, the basis on which was developed our general concept of the Efficiency in the Ordered Linear Spaces and its Applications, supplied by the Ordered Locally Convex Spaces, is represented about the vastness class of the Convex Cones introduced by Professor Isac in 1981, published in 1983, called by us and, officially recognized, as “Isac’s Cone” in 2009, after the acceptance of this last agreed denomination by Professor Isac. To it is devoted this scientific research work, following the content of this International Meeting. All the elements concerning the ordered topological vector spaces used here are in accordance with Nachbin, L., 1965 and Peressini, A., L., 1967.

II. General Efficiency in the Ordered Vector Spaces

Let $E$ be any real or complex vector space ordered by a convex cone $K, K_1$ a non-void subset of $K$ and $A$ a non-empty subset of $E$. The following definition introduces a new concept of the efficiency which generalizes the well known Pareto type efficiency in every ordered Euclidean space and not only.

Definition 1. (Postolică,V., 2002, 2008). We say that $a_o \in A$ is a $K_1$-minimal efficient point of $A$, in notation, $a_o \in MIN(A, K, K_1)$ if it satisfies one of the following equivalent conditions:

(i) $A \cap (a_o - K - K_1) \subseteq a_o + K + K_1$;

(ii) $(K + K_1) \cap (a_o - A) \subseteq -K - K_1$;

In a similar manner one defines the $K_1$-maximal efficient points by replacing $K + K_1$ with $-(K + K_1)$.

The set of such as these points will be denoted by $MAX(A, K, K_1)$. Whenever $K_1 = \{\theta\}$, with $\theta$ the null vector of $E$, we consider that $MIN(A, K, K_1) = MIN(A, K)$ and $MAX(A, K, K_1) = MAX(A, K)$, respectively. All the efficient points of the set $A$ with respect to the convex cone $K$ following $K_1$ are represented by $eff(A, K, K_1) = MIN(A, K, K_1) \cup MAX(A, K, K_1)$. Consequently, $eff(A, K) = MIN(A, K) \cup MAX(A, K)$. Clearly, $A \cap (a_o \mp K) \subseteq a_o \pm K \Rightarrow A \cap (a_o \pm K \mp K_1) \subseteq a_o \mp K \mp K_1 \Rightarrow A \cap (a_o \mp K_1) \subseteq a_o \pm K$,

which suggests other concepts for the efficiency and its approximate term in the general Ordered Vector Spaces.
Remark 1. Obviously, \( a_0 \in \text{eff}(A, K, K_i) \) iff it is a fixed point for at least one of the multifunctions \( F_i : A \to 2^A \) defined by \( F_i(t) = \{ a \in A : A \cap (a \mp K \mp K_i) \subseteq t \pm K \pm K_i \} \), that is, \( a_0 \in F_i(a_0) \), with the corresponding signs. Consequently, for the existence of these general efficient points we can also apply appropriate fixed points theorems concerning the multi-functions (see, for instance, Cardinali, T., Papalini, F., 1994, Park, S., 1992, Patriche, M., 2003, Zhang Cong – Jun, 2005 and any other proper scientific papers).

Remark 2. Németh, A.B., 1989, proved that, whenever \( K_i \subseteq K \setminus \{ \theta \} \), the existence of this new type of the efficient points for the lower bounded sets characterizes the semi-Archimedian Ordered Vector Spaces and the Regular Ordered Locally Convex Spaces.

Remark 3. Whenever \( K \) is pointed, that is, \( K \cap (-K) = \{ \theta \} \), then \( a_0 \in \text{MIN}(A, K, K_i) \) \( (a_0 \in \text{MAX}(A, K, K_i)) \) means that \( A \cap (a_0 \mp K \mp K_i) = \emptyset \) or, equivalently, \((\pm K + K_i) \cap (a_0 - A) = \emptyset \) for \( \theta \not\in K_i \) and \( A \cap (a_0 \mp K \mp K_i) = \{ a_0 \} \), respectively, if \( \theta \in K_i \). Whenever \( K_i = \{ \theta \} \), from the Definition 1 one obtains the usual concept of the efficient (Pareto minimal, optimal or admissible) point : \( a_0 \in \text{MIN}(A, K)(\text{MAX}(A, K)) \) if it fulfills (i), (ii) or everyone of the next equivalent properties:

(iii) \((A \pm K) \cap (a_0 \mp K) \subseteq a_0 \pm K\);

(iv) \( K \cap (a_0 \mp A) \subseteq \mp K\)

This shows that \( a_0 \) is a fixed point for at least one of the following multifunctions:

\[
F_i : A \to A, F_i(t) = \{ a \in A : A \cap (a \mp K) \subseteq t \pm K \},
\]

\[
F_2 : A \to A, F_2(t) = \{ a \in A : A \cap (t \mp K) \subseteq a \pm K \},
\]

\[
F_3 : A \to A, F_3(t) = \{ a \in A : (A \pm K) \cap (a \mp K) \subseteq t \pm K \},
\]

\[
F_4 : A \to A, F_4(t) = \{ a \in A : (A \pm K) \cap (t \mp K) \subseteq a \pm K \},
\]

that is, \( a_0 \in F_i(a_0) \) for every \( i = 1,4 \). If, in addition, \( K \) is pointed, then \( a_0 \in A \) is an efficient point of \( A \) with respect to \( K \) if and only if one of the following equivalent relations holds :

(v) \( A \cap (a_0 \mp K) = \{ \theta \} \);

(vi) \( A \cap (a_0 \mp K \setminus \{ \theta \}) = \emptyset \);

(vii) \((\pm K) \cap (a_0 - A) = \{ \theta \} \);

(viii) \((\pm K \setminus \{ \theta \}) \cap (a_0 - A) = \emptyset \);

(ix) \((A \pm K) \cap [a_0 \mp (K \setminus \{ \theta \})) = \emptyset \).

We also notice that

\[
\text{MIN}(A, K)(\text{MAX}(A, K)) = \bigcap_{[0] = K \subseteq K} \text{MIN} \left( A, K, K_i \right) \left( \bigcap_{[0] = K \subseteq K} \text{MAX} \left( A, K, K_i \right) \right).
\]

Moreover, \( a_0 \in \text{eff}(A, K) \) if only if it is a critical (ideal or balance) point (see, for example, Kim, W. K., Tan, K.K., 2001; Isac, G. 1985; Isac, G., Bulavsky, V. A., Kalashnikov, V., V. 2002; Isac, G., Postolîcă, V., Venzi,L., 2001; Postolîcă, V., 2004 and the corresponding references) for the generalized dynamical systems \( \Gamma_\gamma : A \to 2^A \) defined by \( \Gamma_\gamma(a) = A \cup (a \mp K), a \in A \). In this way , \( \text{eff}(A, K) \) describes the balance extremum moments for \( \Gamma_\gamma \), which in the market context, expresses the competitive equilibrium/non-equilibrium consisting of the general relation price/consumption. Considering \( K_i = \{ \varepsilon \} (\varepsilon \in K \setminus \{ \theta \}) \), one obtains that \( a_0 \in \text{eff}(A, K, K_i) \) if \( A \cap (a_0 - \varepsilon \mp K) = \emptyset \). In all these cases, for the set \( \text{MIN}(A, K, K_i) \) we used the notation \( \varepsilon \in \text{MIN}(A, K) \). It is obvious that

DOI: 10.9790/5728-1302017994
General Efficiency

\[ MIN(A, K) = \bigcap_{\varepsilon \in K(0)} \left[ \varepsilon - MIN(A, K) \right], \]

Let us consider the set \( SMIN(A, K, K_1) = \{ a_1 \in A : A \subseteq a_1 + K + K_1 \} \) of all strong minimum points of \( A \) with respect to \( K \) by \( K_1 \) and \( SMAX(A, K, K_1) = \{ a_2 \in A : A \subseteq a_2 - K - K_1 \} \) the set of all strong maximum points of \( A \) with respect to \( K \) by \( K_1 \), respectively, and 

\[ S(A, K, K_1) = \{ a_1 \in A : A \subseteq a_1 + K + K_1 \} \cup \{ a_2 \in A : A \subseteq a_2 - K - K_1 \} \]

The following theorem shows the immediate connection between the efficiency and the strong optimization through the agency of cone minimal(cone maximal) efficient points.

**Theorem 1.** If \( S(A, K, K_1) \neq \emptyset \), then \( S(A, K, K_1) = eff(A, K, K_1) \).

**Proof.** In fact, we prove that \( SMIN(A, K, K_1) \neq \emptyset \Rightarrow MIN(A, K, K_1) = SMIN(A, K, K_1) \) and \( SMAX(A, K, K_1) \neq \emptyset \Rightarrow MAX(A, K, K_1) = SMAX(A, K, K_1) \), so it is sufficient to show the first implication. Clearly, \( SMIN(A, K, K_1) \subseteq MIN(A, K, K_1) \). Indeed, if \( a_0 \in SMIN(A, K, K_1) \) and \( a \in A \backslash \{ a_0 \} \) are arbitrary elements, then \( a \in a_0 + K + K_1 \), that is, \( a_0 \in MIN(A, K, K_1) \) by virtue of the point (i) contained in the Definition 2. Suppose now that \( \bar{a} \in SMIN(A, K, K_1) \neq \emptyset \) and there exists \( a_0 \in MIN(A, K, K_1) \backslash SMIN(A, K, K_1) \). Out of the fact \( \bar{a} \in SMIN(A, K, K_1) \), it follows that \( a_0 \in a_0 + K + K_1 \), that is, \( \bar{a} \in a_0 + K - K_1 \), from which, since \( \bar{a} \in A \) and \( a_0 \in MIN(A, K, K_1) \), we conclude that \( \bar{a} \in a_0 + K + K_1 \). Therefore, \( A \subseteq \bar{a} + K + K_1 \subseteq a_0 + K + K_1 \), in contradiction with \( a_0 \not\in SMIN(A, K, K_1) \), as claimed.

**Remark 4.** It is obvious that \( SMIN(A, K, K_1) \subseteq eff(A, K, K_1) \). The previous theorem shows that every time there exists at least one strong cone minimum or cone maximum point, the set of all efficient points coincides with the set of all these points, respectively. This is important also for the numerical methods, because if there exist strong efficient points, then these are the only general efficient points. Using this conclusion and the abstract construction given by us in (Postolă, V., 1991, 1988) for the splines in the H-locally convex spaces introduced in (Pecipanu, T., 1969) as separated locally convex spaces with any semi-norm satisfying the parallelogram law, linear topological spaces also studied with strictness in (Kramar, E., 1981), it follows that, the only best simultaneous and vectorial approximation for each element in the direct sum of any (closed) linear subspace and its orthogonal, with respect to a linear (continuous) operator between two arbitrary H-locally convex spaces, is its spline function. We also note that it is possible to have \( S(A, K, K_1) = \emptyset \) and \( eff(A, K, K_1) = A \). Thus, for example, if one considers \( X = R^n (n \in N, n \geq 2) \), \( K = R^n \), \( K_1 = \{(0,\ldots,0)\} \) and for each real number \( c \) we define \( A_{bc} = \{ (x_i) \in X : \sum_{i=1}^{n} x_i = c \} \), \( A_{bc} = \{ (x_i) \in X : \sum_{i=1}^{n} x_i \geq c \} \), \( A_{bc} = \{ (x_i) \in X : \sum_{i=1}^{n} x_i \leq c \} \), then it is clear that
General Efficiency

\[ S\left( A_{bc}, K, K_1 \right) = S\left( A_{bc}, K, K_1 \right) = S\left( A_{bc}, K, K_1 \right) = \emptyset, \]
\[ \text{effect}\left( A_{bc}, K, K_1 \right) = \text{MIN}(A_{bc}, K, K_1) = \text{MAX}(A_{bc}, K, K_1) = A_{bc}, \]
\[ \text{MIN}(A_{bc}, K, K_1) = \text{MAX}(A_{bc}, K, K_1) = A_{bc}, \]

so, by extrapolation,
\[ \text{effect}\left( A_{bc}, K, K_1 \right) = A_{bc} \cup \left\{(+\infty, +\infty, \ldots, +\infty) \right\} \]

and  \[ \text{effect}\left( A_{bc}, K, K_1 \right) = A_{bc} \cup \left\{(-\infty, -\infty, \ldots, -\infty) \right\}. \]

At the same time, in the usual real linear space of all countable sequences, ordered by the convex cone
\[ K = \left\{ (x_n) : n \in N^*, n \geq 2, x_n \geq 0, \forall n \geq 2 \right\}, \]
for  \[ A = \left\{ (x_{na}) : n \in N^*, n \geq 2, \alpha > 0 \right\} \] with
\[ x_{na} = (n-1)^{-\alpha} - n^{-\alpha}, n \in N^*, n \geq 2, \alpha > 0 \] and  \[ K_1 = \left\{ (0, 0, \ldots) \right\}, \]
we have
\[ \text{effect}\left( A, K, K_1 \right) = S(A, K, K_1) = \emptyset. \]
Simple examples show that, in general, the implication
\[ S\left( A, K, K_1 \right) = \emptyset \Rightarrow \text{effect}\left( A, K, K_1 \right) = A \] is not true.

III. Issac’s Cones and the Efficiency

Initially, the next concept of convex cone named by its author nuclear, supernormal (Isac, G., 1980, 1981, 1983, 1985) and, by us, Issac’s cone (Postolică, V., 2009) was introduced in the following context, being the most appropriate for the general efficiency by optimization and conversely (see, for instance, Isac, G. 1980, 1981, 1983, 1985, 1994, 1998, 2003; Isac, G., Bahya, A.O., 2002; Isac, G., Postolică, V., 1993, 2005; Isac, G., Tammer, Chr., 2003 and so on). As we’ll see, to ensure the existence of the efficient points for a non-empty set in an arbitrary ordered Hausdorff locally convex space, the main reason will be to replace the compactness assumption on the set with the completeness hypothesis and the ordering cone to be an Issac’s cone.

**Definition 2.** (Treves, F., 1967). A locally convex space is any couple \((X, \text{Spec}(X))\) which is composed of a real linear space \(X\) and a family \(\text{Spec}(X)\) of seminorms on \(X\) such that:

(i) \(\chi p \in \text{Spec}(X), \forall \chi \in R_+, p \in \text{Spec}(X)\);

(ii) if \(p \in \text{Spec}(X)\) and \(q\) is an arbitrary seminorm on \(X\) such that \(q \leq p\), then \(q \in \text{Spec}(X)\);

(iii) \(\sup(p_1, p_2) \in \text{Spec}(X), \forall p_1, p_2 \in \text{Spec}(X)\) where

\[ \sup(p_1, p_2)(x) = \sup(p_1(x), p_2(x)), \forall x \in X. \]

It is well known that, whenever such a family as this \(\text{Spec}(X)\) is given on a real vector space \(X\), there exists a locally convex topology \(\tau\) on \(X\) such that \((X, \tau)\) is a topological linear space and a seminorm \(p\) on \(X\) is \(\tau\)-continuous iff \(p \in \text{Spec}(X)\). A non-empty subset \(B\) of \(\text{Spec}(X)\) is a base for it if for every \(p \in \text{Spec}(X)\) there exist \(\chi \in B\) such that \(p \leq \chi q\) and \((X, \tau)\) is a Hausdorff locally convex space iff \(\text{Spec}(X)\) has a base \(B\), named Hausdorff base, with the property that
\[ \{x \in X : p(x) = 0, \forall p \in B\} = \{\theta\} \] where \(\theta\) is the null vector in \(X\). In this lecture we will suppose that the space \((X, \tau)\) sometimes denoted by \(X\) is a Hausdorff locally convex space. Every non-empty subset \(K\) of \(X\) satisfying the following properties: \(K + K \subseteq K\) and \(\chi K \subseteq K, \forall \chi \in R_+\) is named convex cone. If, in addition, \(K \cap K = \{\theta\}\), then \(K\) is called pointed. Clearly, any pointed convex cone \(K\) in \(X\) generates an ordering on \(X\) defined by \(x \leq y(x, y \in X)\) iff \(y - x \in K\). If \(X^*\) is the dual of \(X\), then the dual cone of \(K\) is defined by \(K^* = \{x^* \in X^* : x^*(x) \geq 0, \forall x \in K\}\) and its corresponding polar is \(K^0 = -K^*\). We recall that a pointed convex cone \(K \subset (X, \text{Spec}(X))\) is normal with respect to the topology defined by \(\text{Spec}(X)\) if it fulfills one of the next equivalent assertions:

(i) there exists at a base \(\Omega\) of neighborhoods for the origin \(\theta\) in \(X\) such that
\[ V = (V + K) \cap (V - K), \forall V \in \Omega; \]
(ii) there exists a base \(B\) of \(\text{Spec}(X)\) with \(p(x) \leq p(y), \forall x, y \in K, x \leq y, \forall p \in B; \)

DOI: 10.9790/5728-1302017994 www.iosrjournals.org 82 | Page
(iii) for any two nets \( \{x_i\}_{i \in I}, \{y_i\}_{i \in I} \subseteq K \) with \( \theta \leq x_i \leq y_i, \forall i \in I \) and \( \lim y_i = \theta \) it follows that \( \lim x_i = \theta \). In particular, a convex cone \( K \) is normal in a normed linear space \( (E, \| \cdot \|) \) iff there exists \( t \in (0, \infty) \) such that \( x, y \in E \) and \( y - x \in K \) implies that \( \| x - y \| \leq t \| y \| \).

It is well known (Treves, F., 1967) that, the concept of normal cone together with its natural generalizations represents the most important notion in the theory and the applications of the convex cones in the general topological ordered vector spaces. Thus, for example, for every separated locally convex space \( (X, \text{Spec}(X)) \) and any closed normal cone \( K \subseteq (X, \text{Spec}(X)) \) we have \( X^* = K^* - K^* \) (for more details see Hyers, D., H., Isac, G., Rassias, T.M., 1997; Isac, G., 1980). Each pointed convex cone \( K \subseteq (X, \text{Spec}(X)) \) for which there exists a non-empty, convex bounded set \( B \subseteq X \) such that \( 0 \notin B \) and \( K = \bigcup_{\alpha \geq 0} \alpha B \) is called well-based. A cone \( K \subseteq (X, \text{Spec}(X)) \) is well-based iff there exists a base \( B = \{p_i\}_{i \in I} \) of \( \text{Spec}(X) \) and a linear continuous functional \( f \in K^* \) such that for every \( p_i \in B \) there exists \( c_i > 0 \) with \( c_i p_i(x) \leq f(x), \forall x \in K \) (Hyers, D., H., Isac, G., Rassias, T.M., 1997; Isac, G., 1980).

Clearly, every well-based cone is a normal cone, but, in general, the converse is not true, as we can see in the examples below, starting from the next basic notion.

**Definition 3.** (Isac, G., 1981, 1983). In a Hausdorff locally convex space \( (X, \text{Spec}(X)) \) a pointed convex cone \( K \subseteq X \) is nuclear (supernormal) with respect to the topology induced by \( \text{Spec}(X) \) if there exists a base \( B = \{p_i\}_{i \in I} \) of \( \text{Spec}(X) \) such that for every \( p_i \in B \) there exists \( f_i \in X^* \) with \( p_i(x) \leq f_i(x), \forall x \in K \).

**Remark 5.** Initially, the regretted Professor George Isac considered that Treves’ definition was more scientifically productive for its cones. Afterwards, he accepted our proposal. Thus, for the first time, we called such any such cone “Isac’s cone” in (Postolica˘V., 2009), taking into account that the above definition of any locally convex space is equivalent with the following: let \( X \) be a real or complex linear space and \( P = \{p_\alpha : \alpha \in A\} \) a family of seminorms defined on \( X \). For every \( x \in X, \varepsilon > 0 \) and \( n \in \mathbb{N}^+ \) let

\[
V(x; p_1, p_2, ..., p_n; \varepsilon) = \{y \in X : p_\alpha(y - x) < \varepsilon, \forall \alpha = 1, n\},
\]

then the family

\[
\sigma(x) = \{V(x; p_1, p_2, ..., p_n; \varepsilon) : n \in \mathbb{N}^+, \alpha \in P, \alpha = 1, n, \varepsilon > 0\}
\]

has the properties:

\( (V_1) \ x \in V, \forall V \in \sigma(x) \):

\( (V_2) \ \forall V_1, V_2 \in \sigma(x), \exists V_3 \in \sigma(x) : V_3 \subseteq V_1 \cap V_2 \):

\( (V_3) \ \forall V \in \sigma(x), \exists U \in \sigma(x), \ U \subseteq V \) such that \( \forall y \in U, \exists W \in \sigma(y) \) with \( W \subseteq V \).

Therefore, \( \sigma(x) \) is a base of neighborhoods for \( x \) and taking \( \sigma(x) = \{V \subseteq X : \exists U \subseteq V \} \) the set \( \tau = \{D \subseteq X : D \in \sigma(x), \forall x \in D\} \cup \{\emptyset\} \) is the locally convex topology generated by the family \( P \).

Obviously, the usual operations which induce the structure of linear space on \( X \) are continuous with respect to this topology. The corresponding topological space \( (X, \tau) \) is a Hausdorff locally convex space iff the family \( P \) is sufficient, that is, \( \forall x_0 \in X \setminus \{\theta\}, \exists p_\alpha \in P \) with \( p_\alpha(x_0) \neq 0 \). In this context, a convex cone \( K \subseteq X \) is an Isac’s cone iff

\[
\forall p_\alpha \in P, \exists f_\alpha \in X^* : p_\alpha(x) \leq f_\alpha(x), \forall x \in K.
\]

This is an equivalent definition of Isac’s cones in separated locally convex spaces. The best special, refined and non-trivial Isac’s cones classes associated to normal cones in Hausdorff locally convex spaces was introduced and studied in (Isac, G., Bahya, A., O., 2002) as the full nuclear cones family defined as follows: if \( (X, \text{Spec}(X)) \) is an arbitrary locally convex space \( B \subseteq \text{Spec}(X) \) is a Hausdorff base of \( \text{Spec}(X) \) and \( K \subseteq X \) is a normal cone, then for any mapping \( \varphi : B \to K^* \setminus \{0\} \) one says that the set

\[
K_{\varphi} = \{x \in X : p(x) \leq \varphi(p)(x), \forall p \in B\}
\]

is the full nuclear cone associated to \( K \) whenever \( K_{\varphi} \neq \{\theta\} \).

In fact, \( K \) is supernormal iff there exists

DOI: 10.9790/5728-1302017994 www.iosrjournals.org 83 | Page
\( \varphi : P \rightarrow K^* \setminus \{0\} \) such that \( K \subseteq K_\varphi \) (Proposition 3.1 given by Isac, G. and Postolică, V., 2005). In the above equivalent context, if \( \varphi : P \rightarrow K^* \) is a function, then the convex cone \( K_\varphi = \{ x \in X : p_\alpha (x) \leq \varphi (p_\alpha ) (x), \forall p_\alpha \in P \} \) is the full nuclear cone associated to \( K, P \) and \( \varphi \).

Taking into account that in a real normed linear space \( (E, \| \cdot \|) \), a non-empty set \( T \subseteq E \) is called a Bishop-Phelps cone if there exists \( y^* \in \) the usual dual space \( E^* \) of \( E \) and \( \alpha \in (0, 1] \) such that \( T = \{ y \in E : \alpha \| y \| \leq y^* (y) \} \) and the applications of such as these cones in Nonlinear Analysis, including the Optimization programs with vector-valued objective mappings, one concludes that, for Hausdorff locally convex spaces, the full nuclear cones are natural generalizations of Bishop-Phelps cones in normed vector spaces.

The beginning and the considerations in Section 4 of (Isac, G., Bahya, A. O., 2002) suggested us to consider for each function \( \varphi : P \rightarrow K^* \setminus \{0\} \) the full nuclear cone \( K_\varphi = \{ x \in X : p_\alpha (x) \leq \varphi (p_\alpha ) (x), \forall p_\alpha \in P \} \) in order to give the next generalization of Theorem 7 in (Isac,G., Bahya, A.O., 2002), as and extension of the main result indicated by (Isac, G., Postolică, V., 2005), an important link between the efficiency, the full nuclear cones, strong optimization and a significant result concerning the multiple scalarization for this general concept of the efficiency.

**Theorem 2.** If \( K \) is any Isac’s cone in every Hausdorff locally convex space \( (X, P = \{ p_\alpha : \alpha \in A \}) \), then

(i) \( \text{MIN} \left( A, K, K_1 \right) = \bigcup_{\alpha \in A} \text{SMIN} \left( A \cap (a - K - K_1), K_\varphi \right) \);  

(ii) \( \text{MAX} \left( A, K, K_1 \right) = \bigcup_{\alpha \in A} \text{SMAX} \left( A \cap (a + K + K_1), K_\varphi \right) \);  

(iii) \( \text{eff} \left( A, K, K_1 \right) = \bigcup_{\alpha \in A_{\varphi}} \left[ \text{SMIN} \left( A \cap (a - K - K_1), K_\varphi \right) \cup \text{SMAX} \left( A \cap (a + K + K_1), K_\varphi \right) \right] \), for any non-empty subset \( K_1 \) of \( K \).

**Proof.** It follows, mutatis mutandis, the same line as for Theorem 4.3 given by Isac,G. and Postolică, V. in 2005.

**Remark 6.** To obtain (ii) from (i) it is not about of a simple formality by replacing \( K \) with \( (-K) \), since \( (-K)_\varphi = -K_\varphi \). If \( 0 \notin K_1 \), then \( a_0 \in \text{eff}(A,K,K_1) \) implies that \( A \cap (a_0 - K - K_1) = \emptyset \). Therefore, it is not possible to have a \( a_0 \in S(\emptyset,K_\varphi) \). In the case of \( 0 \in K_1 \), then eff\((A,K,K_1)=\text{eff}(A,K)\) and \( a_0 \in \text{eff}(A,K) \) iff \( A \cap (a_0 - K) = \{a_0\} \), so in the right member of the first proved inclusion it can be selected any convex cone, not necessary \( K_\varphi \). The hypothesis \( K \subseteq K_\varphi \) imposed upon the convex cone \( K \) and automatically satisfied since \( K \) is an Isac’s cone was used only to prove the next inclusion, with its natural projection for \( \text{MAX} \left( A, K, K_1 \right) \):  

\( \text{MIN} \left( A, K, K_1 \right) \subseteq \bigcup_{\alpha \in A_{\varphi}} \text{SMIN} \left( A \cap (a - K - K_1), K_\varphi \right) \).

**Corollary 2.1.** For every non-empty subset \( A \) of any Hausdorff locally convex space ordered by an arbitrary Isac’s cone \( K \) with its dual cone \( K^* \) we have

(i) \( \text{MIN} \left( A, K \right) = \bigcup_{\alpha \in A_{\varphi}} \text{SMIN} \left( A \cap (a - K), K_\varphi \right) \);
(ii) \( \text{MAX} (A, K) = \bigcup_{a \in A, \varphi \in P \to K \setminus \{0\}} \text{SMAX} \left( A \cap (a + K), K_{\varphi} \right) \)

(iii) \( \text{eff} (A, K) = \bigcup_{a \in A, \varphi \in P \to K \setminus \{0\}} [\text{SMIN} \left( A \cap (a - K), K_{\varphi} \right) \cup \text{SMAX} \left( A \cap (a + K), K_{\varphi} \right)] \).

Remark 7. The hypothesis of the above theorem involves \( K \) to be pointed. Consequently, \( 0 \in K \) iff \( 0 \in K + K_1 \).

If \( a_0 = S(A \cap (a-K-K_1), K_{\varphi}) \) for some \( \varphi : P \to K \) and \( a \in A \) with \( a = k-k_1, k \in K, k_1 \in K_1 \), then \( K \cap (a_0 - A) = \{0\} \) because \( A \cap (a-K-K_1) \subseteq a_0 + K_{\varphi} \) in any such a case as this. Indeed, let \( x \in K \cap (a_0 - A) \) be an arbitrary element. Then, \( a_0 - x = a-k-k_1 - x \in a-K-K_1 \). Therefore, \( a_0 - x \in a_0 + K_{\varphi} \), that is, \( x \in K_{\varphi} \). For every \( p_\alpha \in P \) we have \( p_\alpha (-x) \leq \varphi (p_\alpha)(-x) = - \varphi (p_\alpha)(x) \leq 0 \). Since \( p_\alpha \) was arbitrary chosen in \( P \) and \( X \) is a Hausdorff locally convex space, it follows that \( x = 0 \).

Remark 8. Clearly, the announced theorem represents a significant result concerning the possibilities of multiple scalarization for the study of the efficiency programs in Hausdorff separated locally convex spaces, as we can see also in the final comments of (Isac, G., Bahya, A.O., 2002) for the particular cases of Hausdorff locally convex spaces ordered by closed, pointed and normal cones.

Remark 9. As an open problem, it is interesting to replace \( K_1 \) with any non-empty subset of an ordered linear space \( X \), under proper hypotheses. In the next considerations we offer significant examples and adequate remarks on the Isac’s cones with the mention that for the existence of the efficient points and important properties of the efficient points sets in separated locally convex spaces ordered by (weak) such as these convex cones, through the agency of the (weak) completeness instead of compactness the reader is referred to (Isac, G., 1981, 1983, 1985, 1994, 1998; Isac, G., Postolica, V., 1993; Postolica, V., 1993, 1994, 1995, 1997, 1999, 2001, 2002, 2009; Truong, X. D. H., 1994 and the references therein).

Theorem 3. (Bahya, A. O., 1989). A convex and normal cone \( K \) in a Hausdorff locally convex space is supernormal if and only if every net of \( K \) weakly convergent to zero converges to zero in the locally convex topology.

Let us consider some pertinent examples which can be also found in (Postolica, V., 2014, 2015, 2016).

1. Any pointed, convex cone, in every Euclidean space \( R^k (k \in N^*) \) is an Isac’s cone.
2. In every locally convex space any well-based convex cone is an Isac’s cone.
3. A convex cone is an Isac’s cone in a normed linear space if and only if it is well-based.
4. Let \( n \in N^* \) be arbitrary fixed and let \( Y \) be the space of all real symmetric \((n, n)\) matrices ordered by the pointed, convex cone
   \[ C = \{ A \in Y : x^T Ax \geq 0, \forall x \in R^n \}. \]
   Then, \( Y \) is a real Hilbert space with respect to the scalar product defined by \( <A, B> = \text{trace} (A \cdot B) \) for all \( A, B \in Y \) and \( C \) is well-based by \( B = \{ A \in C : <A, 1> = 1 \} \) where I denotes the identity matrix.
5. Every pointed, locally or weakly locally compact convex cone in any Hausdorff locally convex space is an Isac’s cone.
6. A convex cone is an Isac’s cone in a nuclear space (Pietch, A., 1972) if and only if it is a normal cone.
7. In any Hausdorff locally convex space a convex cone is an weakly Isac’s cone if and only if it is weakly normal.
8. In \( L^p ([a, b]), (p \geq 1), \) the cone \( K_p = \{ x \in L^p ([a, b]) : x(t) \geq 0 \text{ almost everywhere} \} \) is an Isac’s cone if and only if \( p = 1 \), being well based in this case by the set \( B = \{ x \in K_p : \int_a^b x(t) \, dt = 1 \} \). Indeed, if \( p > 1 \), then the sequence \((x_n)\) defined by
   \[ x_n(t) = \begin{cases} \frac{n^p}{b-a} \cdot t, & 0 \leq t \leq \frac{a+(b-a)}{2n} \\ 0, & 0 < t \leq b \end{cases} \]
   converges to 0 in the weak topology but not in the usual norm topology. Therefore, by virtue of Theorem 1, \( K_p \) is not an Isac's cone. Generally, for every \( p > 1 \), \( K_p \) has a base \( B = \{ x \in K_p : \int_a^b x(t) \, dt = 1 \} \) which is unbounded and any cone generated by a closed and bounded set \( B = \{ x \in B : \int_a^b x(t) \, dt \leq 0 \} \) with \( t \geq 0 \) is certainly an Isac’s cone.

A similar result holds for \( L^p (R) \). Thus, if we consider a countable family \((A_n)\) of disjoint sets which covers \( R \)
such that \((A_n) = 1\) for all \(n \in \mathbb{N}\), where \(\mu\) is the Lebesgue measure, then the sequence \((y_n)\) given by \(y_n(t) = 1\) if \(t \in A_n\) and \(y_n(t) = 0\) for \(t \notin \mathbb{R}A_n\) converges weakly to zero while it is not convergent to zero in the norm topology. Taking into account the above theorem, it follows that the usual positive cone in \(L^1(R)\) is not an Isac’s cone if \(p > 1\), that is, it is not well-based in all these cases. However, these cones are normal for every \(p \geq 1\). The same conclusion concerning the non-supernormality is valid for the positive orthonormal convex cones in the usual Orlicz spaces.

9. In \(L^p(p \geq 1)\) equipped with the usual norm \(\|\cdot\|_p\) the positive cone

\[ C_p = \{\{x_n\} \subseteq C^1: x_n \in C^1\text{ for all } n \in \mathbb{N}\} \text{ is also normal with respect to the norm topology, but it is not an Isac’s cone excepting the case } p = 1. \text{ Indeed, for every } p > 1, \text{ the sequence } (e_n) \text{ having 1 at the n-th coordinate and zeros elsewhere converges to zero in the weak topology, but not in the norm topology and by virtue of Theorem 3 it follows that } C_p \text{ is not an Isac’s cone. For } p = 1, C_p \text{ is well-based by the set } B = \{x \in C: \|x\|_1 = 1\} \text{ and Proposition 5 (Isac, G., 1983) ensures that it is an Isac’s cone. If we consider in this case the locally convex topology in } L^1 \text{ defined by the seminorms } p_d((x_n)) = \sum_{k=0}^{n} |x_k| \text{ for every } (x_n) \in C^1 \text{ and } n \in \mathbb{N}, \text{ which is weaker than its usual weak topology, then the usual positive cone remains an Isac’s cone with respect to this topology (now it is normal in a nuclear space and one applies Proposition 6 of (Isac, G., 1983) but it is not well based. Taking into account the concept of H-locally convex space introduced by Precupanu, T. in 1969 and defined as any Hausdorff locally convex space with the seminorms satisfying the parallelogram law and the property that every nuclear space is also a H-locally convex space with respect to an equivalent system of seminorms (Pietch, A., 1972), the above example shows that in a H-locally convex space a proper convex cone may be an Isac’s cone without to be well-based. Moreover, if we consider in } L^1 \text{ the H-locally convex topology induced by the seminorms }

\[ \tilde{p}_n((x_n)) = \left( \sum_{k=0}^{n} |x_k|^p \right)^{1/p}, \text{ } n \in \mathbb{N}, \text{ } (x_n) \in C^1, \]

then the convex cone \(C_2 = \{(x_n) \in C^1: x_n \in C^1\text{ for all } k \in \mathbb{N}\} \) is normal in the H-locally convex space \((l^1, \{\tilde{p}_n\}_n)\), but it is not a supernormal cone because the same sequence \((e_n)\) is weakly convergent to zero while \(\tilde{p}_n(e_n)\) is convergent to 1 for each \(n \in \mathbb{N}\) and one applies again Theorem 3. Another interesting example of normal cone in a H-locally convex space which is not supernormal is the usual positive cone in the space \(L^2_{loc}(R)\) of all functions from \(R\) to \(C\) which are square integrable over any finite interval of \(R\), endowed with the system of seminorms \(\left\{\tilde{p}_n: n \in \mathbb{N}\right\}\) defined by \(\tilde{p}_n(x) = \left( \int_{-a}^{a} |x(t)|^2 \, dt \right)^{1/2}\) for every \(x \in L^2_{loc}(R)\). In this case, the sequence \((x_n)\) given by:

\[ x_k(t) = \begin{cases} 0, & t \in (-\infty, 0) \cup (1/k, +\infty) \\ \sqrt{k}, & t \in [0, 1/k] \end{cases} \]

converges weakly to zero, but it is not convergent in the H-locally convex topology. The results follows by Theorem 3. It is clear that every weak topology is a H-locally convex topology and, in these cases, the supernormality of convex cones coincides with the normality thanks to the Corollary of Proposition 2 in (Isac, G., 1983).

10. In the space \(C([a, b])\) of all continuous, real valued functions defined on every non-trivial, compact interval \([a, b]\) equipped with the usual supremum norm the convex cone \(K = \{x \in C([a, b]) : x \text{ is concave, } x(a) = x(b) = 0 \text{ and } x(t) \geq 0 \text{ for all } t \in [a, b]\}\) is an Isac’s cone, being well based by the set \(\{x \in K : \text{such that } t_0 \in [a, b] \text{ is an Isac’s cone, being well based by the set } \{x \in K : x(t_0) = 1\}\) for some arbitrary \(t_0 \in [a, b]\) and by the hypothesis that all \(x \in K\) are concave is essential for the supernormality. The convex cone of all nonnegative sequences in the space of all absolutely convergent sequences is the dual of the usual positive cone in the space of all convergent sequences. Consequently, it has a weak star compact base and hence it is a weak star supernormal cone.

11. In \(L^1\) or in \(C_0\) equipped with the supremum norm, the convex cone consisting of all sequences having all partial sums non-negative is not normal, hence it is not supernormal.

12. In every Hausdorff locally convex space any normal cone is an Isac’s cone with respect to the weak topology. In every locally convex lattice which is a (L)-space the ordering cone is supernormal (see also the Example 7 given by Isac, G. in 1994).

13. If we consider the space of all locally integrable functions on a locally compact space \(Y\) with respect to a Radon measure \(\mu\) endowed with the topology induced by the family of seminorms \(\{p_{\lambda}\}\) where \(p_{\lambda}(f) = \int |f(x)|^p \, \mu(dx)\), then the sequence \((x_n)\) given by:

\[ x_k(t) = \begin{cases} 0, & t \in (-\infty, 0) \cup (1/k, +\infty) \\ \sqrt{k}, & t \in [0, 1/k] \end{cases} \]

converges weakly to zero, but it is not convergent in the H-locally convex topology. The results follows by Theorem 3. It is clear that every weak topology is a H-locally convex topology and, in these cases, the supernormality of convex cones coincides with the normality thanks to the Corollary of Proposition 2 in (Isac, G., 1983).

14. In \(L^1\) or in \(C_0\) equipped with the supremum norm, the convex cone consisting of all sequences having all partial sums non-negative is not normal, hence it is not supernormal.

15. In every Hausdorff locally convex space any normal cone is an Isac’s cone with respect to the weak topology.

DOI: 10.9790/5728-1302017994 www.iosrjournals.org
General Efficiency

\[ \int_{A} f(x) \, d\mu \] for every non-empty and compact subset \( A \) of \( Y \) and every locally integrable function \( f \), then the
convex cone \( K = \{ f: f(x)\geq 0, \, x \in Y \} \) is
supernormal.

16. If \( Z \) is any locally convex lattice ordered by an arbitrary convex cone \( K \) and \( Z^\tau \) is its topological dual
ordered by the corresponding dual cone \( K^\tau \), then the cone \( K \) is
supernormal with respect to the locally convex topology defined on \( Z \) by
the neighbourhood base at the origin \( \{ [-f, f]^\tau \}_{f \in K} \).

17. In every regular vector space \((E, K)\) (that is, the order dual \( E^\tau \) separates the points of \( E \)) with the
property that \( E = K - K \) the convex cone \( K \) is supernormal with respect to
the topology defined in the preceding example.

18. Any semicompacte cone in a Hausdorff locally convex space is an Isac’s cone (for this concept see
the Example 11 of Isac, G., 1994).

Remark 10. Clearly, if a convex cone \( K \) is supernormal in a normed space, then \( K \) admits a strictly positive,
linear and continuous functional, that is, there exists a linear, continuous functional \( f \) such that \( f(k) > 0 \) for all \( k \in K \). Generally, the converse is not true even in a Banach space as we can see in the following examples:

19. If one considers in the usual space \( L^p \) \( (1 \leq p \leq \infty) \) the convex cone
\[ K = \ell^p_+ = \{ x = (x_i) \in \ell^p : x_i \geq 0 \text{ for every } i \in \mathbb{N} \} \]
of infinite vectors with non-negative components, then
the functional \( \varphi(k) \) defined by \( \varphi(k) = \sum_{i=1}^\infty k_i \) for any \( k = (k_i) \in \ell^p \) is linear, continuous and strictly positive. But, as we have
seen in the above considerations (Example 9), this cone is supernormal if and only if \( p = 1 \).

20. Let \( K \) be the usual positive cone \( L^p_+ = \{ x \in L^p([a, b]) : x(t) \geq 0 \text{ almost everywhere} \} \) in \( L^p([a, b]) \) \( (1 \leq p \leq \infty) \). Then, the
linear and continuous functional \( \psi \) on \( L^p([a, b]) \) given by \( \psi(x) = \int_a^b x(t) \, dt \) for every \( x \in L^p([a, b]) \) is strictly
positive on \( K \) while \( K \) is supernormal (see the above Example 8) if and only if \( p = 1 \).
Therefore, \( L^1_+ \) and \( L^\infty_+ \) are supernormal cones with empty topological interiors and for every \( p \in (1, \infty) \) it follows that \( L^p_+ \) and \( L^\infty_+ \) are normal cones with empty interiors which are not supernormal. Hence, these convex cones are not well based. A very simple example of supernormal cones having non-empty topological interior is \( R^*_n (n \in \mathbb{N}^\ast) \).

Remark 11. In the order complete vector lattice \( B([a, b]) \) of all bounded, real valued functions on a compact
non-singleton interval \([a, b]\) endowed with its usual norm the standard positive cone \( K = \{ u \in B([a, b]) : u(t) \geq 0 \text{ for all } t \in ([a, b]) \} \) is normal but it has not a base, that is, it is not supernormal. However, this cone has non-empty interior. If we consider the linear space \( L^1 \) endowed with the separated locally convex topology generated
by the family \( \{ p_n : n \in \mathbb{N} \} \) of seminorms defined by \( p_n(x) = \sum_{i=1}^n |x_i| \) for every \( x = (x_i) \in L^1 \), then the convex cone \( K = \{ x = (x_i) \in L^1 : x_i \geq 0 \text{ whenever } k \in \mathbb{N} \} \) is supernormal but it is not well based.

IV. Some conclusions

The natural context of supernormality (nuclearity) for convex cones is any separated locally convex
space. Isac, G., introduced the concept of “nuclear cone” in 1981, published it in 1983 and he showed that in a
normed space a convex cone is nuclear if and only if it is well based or equivalently if it is “with
plastering”, the last concept being defined by Krasnoselski, M. A. in fifties (see, for example , Krasnoselski, M. A., 1964
and so on). Such a convex cone was initially called “nuclear cone” by Isac, G. (1981) because in every nuclear
space (Pietch, A., 1972) any normal cone is a nuclear cone in Isaac’s sense (Proposition 6 of Isac, G., 1983).
Afterwards, since the nuclear cone introduced by Isac appears as a reinforcement of the normal cone, it was
called supernormal. The class of supernormal cones in Hausdorff locally convex spaces was initially imposed by
the theory and the applications of the efficient (Pareto minimum type) points (especially existence conditions
based on completeness instead of compactness were decisive together with the main properties of the efficient
points sets), the study of critical points for dynamical systems and conical support points and their importance
was very well illustrated by important results, examples and comments in the specified references and in
other connected papers. It is also very significant to mention again that the concept of supernormality introduced by
Isac, G. (1981) is not a simple generalization of the corresponding notion defined in normed linear spaces by
Krasnoselski, M. A. and his colleagues in the fifties. Thus, for example, Isaac’s supernormality attached to the
convex cones has his sense in every Hausdorff locally convex space identically with the well known
Grothendieck’s nuclearity. By analogy with the fact that a normed space is nuclear in Grothendieck’s sense if
and only if it is isomorpe with an usual Euclidean space, a convex cone is supernormal in a normed space if
and only if it is well based, that is, it is generated by a convex bounded set which does not contain the origin in
its closure. Beside Pareto type optimization, we also mention Isaac’s significant contributions, through the
agency of supernormal cones, to the convex cones in product linear spaces and Ekeland’s variational type

DOI: 10.9790/5728-1302017994 www.iosrjournals.org 87 | Page
principles (Isac.G., 2003; Isac.G., Tammer, Chr., 2003). Therefore, the more appropriate background for Isac’s cones is any separated locally convex space. On the other hand, the extension in real or complex vector spaces of this notion can be done since any real or complex vector space can be considered as a locally convex space with respect to the locally convex topology generated by the family of the seminorms originated in the Minkowski functionals associated to the algebraic and geometric concepts of the convex hulls for the balanced (circled) and absorbing sets containing its origin (Postolică, V., 2014). The behavior of Isac’s cones in some variable locally convex topologies, especially in duality, is also interesting (Postolică, V., 2015).

**Definition 4.** (Postolică, V., 1995). A nonempty set $B$ of a topological vector space $X$ ordered by a convex cone $K$ is called $K$-bounded if there exists $B_0 \subset X$ bounded so that $B \subset B_0 \pm K$ and $K$-closed if its conical extension $B \pm \bar{K}$ is closed, where $\bar{K}$ signifies the topological closure of $K$.

A synthesis concerning the existence and significant properties of the efficient points are given in the next theorem.

(i) If $K$ is an Isac’s cone in a Hausdorff locally convex space $X$, $A, B \subset X$ are nonempty subsets positioned by $A \subset B \subset A + K (A \subset B \subset A - K)$ and $B \cap (A_0 - K) (B \cap (A_0 + K))$ is a bounded and complete set for at least one nonempty set $A_0 \subset A$, then $\text{MIN}(A, K) \neq \emptyset (\text{MAX}(A, K) \neq \emptyset)$;

(ii) if $X$ is a quasi-complete separated locally convex space, that is, any non-empty bounded and closed subset is complete and $K$ is a closed Isac’s cone in $X$, then for every bounded and $K$-closed non-empty set $A$ of $X$ we have $\text{MIN}(A, K) \neq \emptyset$, $A \subset \text{MIN}_K(A) + K (A \subset \text{MAX}(A) - K)$ (the domination property), $\text{MIN}_K(A) + K = A + K (\text{MAX}(A, K) - K = A - K)$ and $\text{MIN}(A, K) (\text{MAX}(A, K))$ is $K$-bounded and $K$-closed;

(iii) according to the same hypotheses from (ii), $\text{MIN}(A, K) \neq \emptyset (\text{MAX}(A, K) \neq \emptyset)$ for any nonempty subset $A$ with $B \cap (A_0 - K) (B \cap (A_0 + K))$ $K$-bounded and $K$-closed set whenever $A_0 \subset A \subset X$ and $A \subset B \subset A + K (A \subset B \subset A - K)$, with the corresponding implications for $\text{Eff}(A, K)$.

V. Efficiency and Choquet Boundaries

**Definition 5.** (Postolică, V., 2008) A real function $f : X \rightarrow R$ is called $(K + K_1)$-increasing ($K + K_1$-decreasing) if $f(x_1) \geq f(x_2)$ whenever $x_1, x_2 \in X$ and $x_1 \in x_2 + K_1 + K (x_1 \in x_2 - K_1 - K)$.

Obviously, every real increasing (decreasing) function defined on any linear space ordered by an arbitrary convex cone $K$ is $K + K_1$-increasing ($K + K_1$-decreasing), for each non-empty subset $K_1$ of $K$.

The next coincidence of the efficient points sets and the Choquet boundaries generalizes the main result given by Bucur, I. and Postolică, V., 1994, and can not be obtained as a consequence of the Axiomatic Potential Theory.

**Theorem 5.** (Postolică, V., 2008, 2009). If $A$ is any nonvoid, compact subset of every Hausdorff linear topological vector space $X$ and

(i) $K$ is an arbitrary, closed, convex, pointed cone in $X$;

(ii) $K_1$ is a nonempty subset of $K$ such that $K + K_1$ is nonempty with respect to the separated topology on $X$.

Then, $\text{MIN}(A, K, K_1) (\text{MAX}(A, K, K_1))$ coincides with the Choquet boundary $\partial_{\text{MIN}} A(\partial_{\text{MAX}} A)$ of $A$ with respect to the convex cone $S_1 (S_2)$ of all $K + K_1$-increasing ($K + K_1$-decreasing) real continuous functions on $A$. Consequently, each of these sets, endowed with the corresponding trace topology, is a Baire space and a $G_\delta$-subset of $X$ whenever $(A, \tau_A)$ is metrizable. Moreover, $\text{Eff}(A, K, K_1) = \partial_{\text{MIN}} A(\partial_{\text{MAX}} A)$.

**Corollary 5.1.**

(i) If for every $f \in C(A)$ one denotes $\overline{f}(a) = \sup \{ f(a') : a' \in A \cap a + K + K_1 \}$ and $\overline{\overline{f}}(a) = \sup \{ f(a') : a' \in A \cap a - K + K_1 \}$, then $\text{Eff}(A, K, K_1) = \bigcup_{a \in A} \{ f \} (a) = \overline{f}(a) \overline{\overline{f}}(a), \forall f \in C(A)$;

(ii) $\text{MIN}(A, K, K_1) (\text{MAX}(A, K, K_1), \text{MIN}(A, K, K_1)) (\text{MAX}(A, K, K_1)) \cap \{ a \in A : s(a) \leq 0 \} (s \in S_1)$ are compact sets with respect to the Choquet’s topology and as usual compact subsets of $A$.
Remark 12. Generally, \( MIN(A, K, K_i) \) coincides with the corresponding Choquet boundary of \( A \) only with respect to the convex cone of all real, continuous and \( K + K_i \)-increasing (\( K + K_i \)-decreasing) functions on \( A \). Thus, for example, if \( A \) is any non-empty, compact and convex subset of every Hausdorff locally convex space and \( S = \{ f : A \rightarrow R | f \text{ is continuous and concave} \} \), then its Choquet boundary with respect to \( S \) coincides with the set \( ex(A) \) of all extreme points \( x \in A \), that is, if \( y, z \in A \) and there exists \( \alpha \in (0, 1) \) with \( \alpha x + (1 - \alpha) y = z \), then \( y = z = x \). The hypothesis of concavity imposed on the functions is essential for the validity of this result. Generally, even in the finite dimensional cases, an extreme point for a compact convex set is not necessary an efficient point and conversely.

Remark 13. The largest class \( \zeta \) of convex cones ensuring the existence for the efficient points in all non-empty compacts subsets of every separated topological vector space was defined by Sterna – Karwat, A., 1986 as follows: if \( V \) is an arbitrary Hausdorff topological vector space, a convex cone \( C \) belongs to \( \zeta \) iff for every closed vector subspace \( L \) of \( V \), \( C \cap L \) is a vector subspace whenever its closure \( C \cap \overline{L} \) is a vector subspace.

As we have already specified before Theorem 5, there exists more general conditions than compactness imposed upon a non-empty set \( A \) in a separated locally convex space ordered by a convex cone \( K \) ensuring that \( eff(A, K) \neq \emptyset \). Perhaps our coincidence result suggests a natural extension of the Choquet boundary at least in these cases. Anyhow, Theorem 5 represents an important link between Vector Optimization and Potential Theory and a new way for the study of the properties of efficient points sets and the Choquet boundaries. Indeed, one of the main question in Potential Theory is to find the Choquet boundaries. This fact is relatively easy for particular cases but, in general, it is an unsolved problem. Since in a lot of cases the efficient points sets contain dense subsets which can be identified by adequate optimization methods, it is possible to determine the corresponding Choquet boundaries in all these situations. Consequently, our coincidence result has its practical consequences at first for the Axiomatic Theory of Potential and its applications. At the same time, by the above coincidence result, the Choquet boundaries offer important properties for the efficient points sets.

VI. Best Approximation in Locally Convex Spaces. Efficiency by Splines in H-locally Convex Spaces

We conclude this research report with some topics on the best approximation (simultaneous and vectorial) in locally convex spaces and the efficiency (optimization) by splines in H-locally convex spaces.

Let \( X \) be a Hausdorff locally convex space with the topology induced by a family \( P = \{ p_a : a \in I \} \) of seminorms, \( x_0 \in X \) and \( G \) a non-empty subset of \( X \).

**Definition 6.** (Isac, G., Postoliciă, V., 1993) \( g_0 \in G \) is said to be a best simultaneous approximation for \( x_0 \) by the elements of \( G \) with respect to the family \( P \) (abbreviated \( g_0 \) is a \( P \)-b.s.a. of \( x_0 \)) when \( p_a(x_0 - g_0) \leq p_a(x_0 - g) \) for all \( g \in G \) and \( p_a \in P \).

If, in addition, each element \( x \in X \) possesses at least one \( P \)-b.s.a. in \( G \), then the set \( G \) is called \( P \)-simultaneous proximinal.

**Definition 7.** (Isac, G., Postoliciă, V., 1993) \( g_0 \in G \) is said to be a best vectorial approximation of \( x_0 \) by \( G \) with respect to \( P \) (abbreviated \( g_0 \) is a \( P \)-b.v.a. of \( x_0 \)) if \( (p_a(x_0 - g_0)) \in MIN(\{ p_a(x_0 - g) : g \in G \}) \) where \( K = \mathbb{R}_+^I \).

If, in addition, each element \( x \in X \) possesses at least one \( P \)-b.v.a. in \( G \), then the set \( G \) is called \( P \)-vectorial proximinal. Several original results and properties concerning these notions were given in our above mentioned book.

Concerning the H-locally convex spaces, it is known that this concept of was introduced and studied for the first time by Pecunaru, T. (1969) and defined as any Hausdorff locally convex space with the seminorms satisfying the parallelogram law. At the same time, we introduced the notion of spline function in H-locally convex space (Postoliciă, V., 1981) and we established the basic properties of approximation and optimal interpolation for these splines. Our splines are natural extensions in H-locally convex spaces of the usual abstract splines which appear in any Hilbert space like the minimizing elements for a seminorm subject to the restrictions given by a set of linear continuous functionals.

So, let now \( (X, P = \{ p_a : a \in I \}) \) be a H-locally convex space with each seminorm \( p_a \) being induced by a scalar semiprodutct \( (< , >_a) \) \( a \in I \) and \( M \) a closed linear subspace of \( X \) for which there exist a H-locally convex space \( (Y, Q = \{ q_a : a \in I \}) \) with each seminorm \( q_a \in Q \) generated by a scalar semiprodutct \( < , >_a \) \( a \in I \) and a linear (continuous) operator \( U : X \rightarrow Y \) such that \( M = \{ x \in X : (x, y)_a = <UX, Uy>_a, \forall a \in I \} \).

The space of spline functions with respect to \( U \) was defined by Postoliciă, V. (1981) as the \( U \)-orthogonal of \( M \), that is,
General Efficiency

\[ M^\perp = \{ x \in X : \langle U_x, U_z \rangle \leq 0, \quad \forall \ z \in M, \ a \in I \}. \] Clearly, \( M^\perp \) is the orthogonal of \( M \) in the H-locally convex sense.

Let us consider the direct sum \( X' = M \oplus M^\perp \) and for every \( x \in X' \), we denote its projection onto \( M^\perp \) by \( s_x \).

Then, taking into account the Theorem 4 obtained by Postolica, V. in 1981, it follows that this spline is a best simultaneous U-approximation of \( x \) with respect to \( M^\perp \) since it satisfies all the next conditions:

- \( p_a(x - s_x) \leq p_a(x - y) \quad \forall \ y \in M^\perp, \ p_a \in P \).

Moreover, following the definition of the approximate efficiency, the results given in Chapter 3 of (Isac, G., Postolica, V., 1993) and the conclusions obtained by (Postolica, V., 1981, 1993, 1998), we have

**Theorem 6.**

(i) for every \( x \in X' \) the only elements of best simultaneous and vectorial approximation with respect to any family of seminorms which generates the H-locally convex topology on \( X \) by the linear subspace of splines are the spline functions \( s_x \). Moreover, if \( M \) and \( M^\perp \) supply an orthogonal decomposiion for \( X \), that is \( X = M \oplus M^\perp \), then \( M^\perp \) is simultaneous and vectorial proximinal;

(ii) if \( K = R^1 \), then for each \( s \in M^\perp \), every \( s \in M^\perp \) is the only solution of following optimization problem \( \text{MIN} \{ (q_a(U(h-s)) : h \in X' \text{ and } h \cdot s \in M \}, K \}; \)

(iii) for every \( x \in X' \) its spline function \( s_x \) is the only solution for the next vectorial optimization problems:

\[ \text{MIN} \{ (q_a(U(h-x)) : h \in M^\perp \}, K \}, \text{MIN} \{ (p_a(x-y)) : y \in M^\perp \}, K \}, \text{MIN} \{ (q_a(U(y)) : y-x \in M \}, K \}. \]

Finally, let us consider two numerical examples in which, following Postolica, V. (1981), Isac, G., Postolica, V. (1993) and Postolica, V., (1998), we specify the expressions of splines and \( M \) and \( M^\perp \) realize orthogonal decompositions.

**Example 1.** Let \( X = H^m(R) = \{ f \in C^{m-1}(R) : f \text{ is absolutely continuous and } f^{(m)} \in L^2_{\text{loc}}(R) \}, m \geq 1 \) endowed with the H-locally convex topology generated by the scalar seminorms

\[ (x, y) = \sum_{k=0}^{n-1} [x^{(k)}(k) y^{(k)}(k) + x^{(k)}(-k) y^{(k)}(-k)] + \int_{-\infty}^{k} x^{(0)}(t) y^{(0)}(t) dt, \]

\( k=0,1,2, \ldots \)

If \( U : X \to Y \) is the derivation operator of order \( m \), then

\( M = \{ x \in H^m(R) : x^{(0)}(n) = 0, \quad \forall n \geq 0, \ m - 1, \ n \in Z \} \)

and \( M^\perp = \{ s \in H^m(R) : \int_{-\infty}^{k} s^{(m)}(t) x^{(m)}(t) dt, \quad \forall x \in M, k=0,1,2, \ldots \} \)

We proved in (Postolica, V., 1981) that

\( M^\perp = \{ s \in H^m(R) : s_{(0,n+1)} \} \)

is a polynomial function of degree \( 2m-1 \) at most and if \( y = (y_a), y' = (y'_a), y'' = (y''_a), \)

\( y^{(m)} = (y^{(m-1)}_a) \)

are \( m \) sequences of real numbers, then there exists an unique spline \( S \in M^\perp \) satisfying the following conditions of interpolation: \( S^{(k)} = y^{(k)}(n) \) whenever \( h=0, m-1 \) and \( n \in Z \). Moreover, we observed in the paragraph 3 of (Isac, G., Postolica, V., 1993) that any spline function \( S \) such as this is defined by

\[ S(x) = p(x) + \sum_{k=0}^{n-1} c_1^{(0)}(x-1) 2^{m-1} + \sum_{k=0}^{n-1} c_2^{(0)}(x-2) 2^{m-1} + \ldots + \sum_{k=0}^{n-1} c_0^{(0)}(x) 2^{m-1} + \ldots \]

where \( u = \frac{1+u}{2} \) for every real number \( u, p \) is a polynomial function of degree \( 2m-1 \) at most perfectly determined by the conditions \( p^{(b)}(0) = y_0^{(b)} \) and \( p^{(b)(1)} = y_1^{(b)} \) for all \( h=0, m-1 \) and the coefficients \( c^{(h)}_u \) are successively given by the general interpolation.
Therefore, for every function \( f \in H^n(R) \), there exists an unique function denoted by \( S_i \in M^\perp \) such that \( S_i^{(n)}(x) = f^{(n)}(x) \), \( \forall \ h=0, m - 1 \) and \( n \in Z \). Hence, in this case, \( M \) and \( M^\perp \) give an orthogonal decomposition for the space \( H^n(R) \).

**Example 2.** Let \( X = F_m = \{ f \in C^{m-1}(R); f^{(m-1)} \text{ is locally absolutely continuous and } f^{(m)} \in L^2(R) \} \) endowed with the \( H \)-locally convex topology induced by the scalar semiproducts

\[
(x,y)_n = x(n)y(n) + \int_R x^{(m)}(t) y^{(m)}(t) dt, \ n \in Z, \ Y = L^2(R) \text{ with the topology generated by the inner product } (x,y)_n = \int_R x(t)y(t) dt, \ n \in Z \text{ and } U:X \rightarrow Y \text{ be the derivation operator of order } m. \text{ Then, } M = \{ x \in F_m; x(n) = 0 \text{ for all } n \in Z \} \text{ and } M^\perp = \{ s \in F_m; \int_R x^{(m)}(t) y^{(m)}(t) dt = 0 \text{ for every } x \in M \}.
\]

In a similar manner as in Example 1 it may be proved that \( M^\perp \) coincides with the class of all piecewise polynomial functions of order \( 2m \) (degree \( 2m-1 \) at most) having their knots at the integer points. Moreover, for every function \( f \in F_m \) there exists an unique spline function \( S_i \in M^\perp \) which interpolates \( f \) on the set \( Z \) of all integer numbers, that is, \( S_i \) satisfies the equalities \( S_i(n) = f(n) \) for every \( n \in Z \), being defined by

\[
S_i(x) = p(x) + a_1(x-1)^{2m-1} + a_2(x-2)^{2m-1} + \ldots + a_n(x-n)^{2m-1} + a_{n+1}(x-(n+1))^{2m-1} + \ldots
\]

where \( u_i \) has the same signification as in Example 1, the coefficients \( a_n (n \in Z) \) are successively and completely determined by the interpolation conditions \( S_i(n) = f(n), n \in Z \{0, 1\} \) and \( p \) is a polynomial function satisfying the conditions \( p(0) = f(0) \) and \( p(1) = f(1) \). The uniqueness of \( S_i \) is ensured in Theorem 2 given by (Postoloi, V., 1981).

Thus, \( M \) and \( M^\perp \) give an orthogonal decomposition of the space \( F_m \) and, as in the preceding example, \( M^\perp \) is simultaneous and vectorial proximinal with respect to the family of seminorms generated by the above scalar semiproducts.

**Remark 14.** Our examples show that the abstract construction of splines can be used to solve also several frequent problems of optimal interpolation and approximation, having the possibility to choose the spaces and the scalar semiproducts. It is obvious that for a given (closed) linear subspace of a \( H \)-locally convex space \( X \) such a \( H \)-locally convex space \( Y \) (respectively, a linear (continuous) operator \( U:X \rightarrow Y \)) would not exist. Otherwise, the problem of best vectorial approximation by the corresponding orthogonal space of any (closed) linear subspace \( M \) for the elements in the direct sum \( M \oplus M^\perp \) might be always reduced to the best simultaneous approximation. But, in general, such a possibility doesn’t exist. Even in a \( H \)-locally convex space it is possible that there exist best vectorial approximations and the set of all best simultaneous approximations to be empty for some element of the space. We confine ourselves to mention the following simple example.

**Example 3.** Let \( X = R^N \) endowed with the topology generated by the family \( P = \{ p_i; i \in N \} \) of seminorms defined by \( p_i(x) = |x_i| \) \( (i \in N) \) for every

\[
x = (x_i) \in X \text{ and } G = \{(x_i) \in X; x_i \geq 0 \text{ whenever } i \in N \text{ and } \sum_{i \in N} x_i = 1 \}
\]

\( X \) is a \( P \)-simultaneous strictly convex (Isac, G., Postoloi, V., 1993) \( H \)-locally convex space. Nevertheless, every element of \( G \) is \( P \)-b.v.a. for the origin while its corresponding set of the best simultaneous approximations with respect to \( P \) is empty.

**VII. Some Open Problems**

The above context of research suggests immediately the following open problems.

**Op. 5.1.** If \( \text{eff}(A, K) \neq \emptyset \) there exist a Hausdorff locally convex space \( Y \), an Isac’s cone \( K_0 \) in \( Y \) and a non-empty set \( A_0 \subset Y \) with \( \text{eff}(A, K) = \text{eff}(A_0, K_0) \) (or, at least, \( \text{eff}(A, K) \) to be dense in \( \text{eff}(A_0, K_0) \))?
General Efficiency

Op. 5.2. If \( \text{eff} (A, K) \neq \emptyset \), there exist a separated locally convex space \( X_1 \), a (pointed), convex cone \( K_1 \) in \( X_1 \) and a compact set \( A \subset X_1 \) such that \( \text{eff} (A, K) = \text{eff} (A, K_1) \) (at least \( \text{eff} (A, K) \) to be dense in \( \text{eff} (A, K_1) \)) or conversely?

Op. 5.3. If \( T \) is a Hilbert space, \( K \) is a closed, convex, pointed cone in \( T \) and \( A \) is a non-empty, closed, convex subset of \( T \), does \( \text{eff} (A, K) \) preserve the property of coincidence with the corresponding Choquet boundary as in the above theorem?

Op. 5.4. The same question for each of the following cases:
(i) \( T \) is a quasi-complete locally convex space; \( K \) is an Isac’s cone; \( A \) is a \( K \)-bounded and \( K \)-closed set in \( T \) (Postolică, V., 1995).
(ii) \( T \) is a quasi-complete locally convex space, the closure \( \bar{R} \) of \( K \) has the properties given in (Truong, X., D. H., 1994) and \( A \) is a \( K \)-bounded and \( K \)-closed subset in \( T \).

VIII. Future Research Directions

This research work can also be considered as a study in which the approximate solutions including those usual to vector optimization programs in ordered (topological) vector spaces are investigated. The listed properties of these solutions allow developments. Several new facts about the relationships between the approximate efficiency and the scalarized problems can be formulated. As we have specified, the family of Isac’s cones represent the largest class of ordering cones in Hausdorff locally convex spaces ensuring the existence and the adequate properties of the efficient points sets involved in optimization, following different completeness types instead of compactness. Consequently, one of the main goal of the next research is to identify new applications of Isac’s cones. The given strong connection by coincidence between the approximate solutions and Choquet’s boundaries for non-empty compact sets can be extended to non-compact sets.
