1Department of Plant Science and Biotechnology, Faculty of Biological Science, University of Port Harcourt, Rivers state- Nigeria

Abstract: Changes in the Amino acid and Protein content of Jatropha curcas induced by Fusarium oxysporum and Macrophomina phaseolina, was carried out using the Association of Official Analytical Chemist method. The Physic nut seeds (Jatropha curcas L) were collected from Federal College of Forestry, Jos, Plateau State. This was carried at the Mycology/Plant Pathology and Physiological Unit of the Department of Plant Science and Biotechnology, University of Port-Harcourt. The results of the total amino acids of the fungi inoculated and uninoculated control Jatropha curcas seeds showed that there was significant reduction (P=0.05) in total amino acids of seeds inoculated with Fusarium oxysporum (91.59g/100g protein) and Macrophomina phaseolina (90.41g/100g protein) compared to uninoculated control (93.23g/100g protein). The changes in the amino acid and protein levels of the seeds as a result of the activities of these fungi are discussed.

Keywords: Amino acid content, Jatropha curcas, Pathogenic fungi, Protein content

I. Introduction

Jatropha plant has been found for using on different aspects in different communities in the world. It has been found that the plant is used as an ornamental purpose, chiefly in Africa and America, growing in gardens for their ornamental foliage and flowers. It is also commonly grown as a live hedge around agricultural fields as it can be easily propagated by seeds or branch cutting as is not browsed by goats or cattle. It can be cut or lopped at any desired height and is well adapted for hedges around agricultural fields.[1] (Gubitz et al, 1999). The most important uses of the plant is its use for biodiesel production.

Jatropha is often described as having a low nutrient requirement because it is adapted to growing in poor soils. However, growing a productive crop requires correct fertilization and adequate rainfall or irrigation. Equally, high levels of fertilizer and excessive irrigation can induce high total biomass production at the expense of seed yield. Unfortunately, there is insufficient data on response to fertilizer under different growing conditions for it to be possible to make specific recommendations for optimal crop nutrition. On wasteland in India,[2] Ghosh et al. (2007) found that 3.0 tonnes per ha of Jatropha seed cake (also known as “press” cake), containing 3.2 percent N, 1.2 percent P₂O₅ and 1.4 percent K₂O, increased yields significantly when applied to young plants – by +120 percent and +93 percent at two different planting densities. A trial at the International Crops Research Institute for the Semi-Arid Tropics (ICRISAT) in India showed increasing yield with fertilization to an optimum level (T3), but that over-application depressed yields.

The optimum levels of inorganic fertilizers have been seen to vary with the age of the tree[3] (Achten, 2008). Site-specific fertilizer trials need to be established for trees of different ages and over a number of seasons. An analysis of the nutrient value of harvested fruit indicates the application rate of nutrients required to maintain soil fertility levels, assuming all other biomass is retained in the field. From the nutrient composition calculated by [4]Jongschaap et al. (2007), the fruit equivalent of 1.0 tonne of dry seed per ha removes 14.3–34.3 kg of N, 0.7–7.0 kg of P, and 14.3–31.6 kg of K per ha. Mycorrhizal soil fungi are generally known to improve a plant’s ability to absorb mineral nutrients and water from the soil, and to increase drought and disease resistance. The Energy and Resources Institute (TERI) in India has developed mycorrhizal inoculations for jatropha that improve germination and gives earlier fruiting and higher yields.[5] (Sharma 1977, cited Jongschaap, 2007) found increased uptake of P and micronutrients.

However, fungi growing on stored seeds, can reduce the germination rate along with loss in the quantum of carbohydrate, protein and total oil content, induces moisture content, free fatty acid content enhancing other biochemical changes of seeds. Due to its economic, nutritional and agricultural importance a study is carried out to find out the effect of the above fungi on the amino acid and protein content of Jatropha curcas seed.
II. Materials And Methods

2.1 Isolation and identification of fungi.

The fungi used in this study *Fusarium oxysporum* and *Macrophomina phaseolina* were isolated from the apparently healthy seeds using the Standard Blotter method recommended by the international Seed Testing Association [6](ISTA, 1976 and Agar method [7](Klement and Voros, 1974). The fungi were identified under a Stereobinocular microscope based on their habit characteristics. Slides were made to confirm identification following descriptions by International Mycological Institute (IMI fungi Descriptions). Pure, single spore cultures of each fungi were obtained by growing them on Potato Dextrose Agar (PDA). The cultures were left in a sterile incubator at room temperature (28±2°C) for 5-7 days to allow for the growth of fungi and were used as inoculum.

2.2 Inoculation of Seeds with Fungi

Fifty grams of healthy *Jatropha curcas* seeds were weighed out into 250ml conical flasks, plugged with non-absorbent cotton wool and covered with foil and then autoclaved at 121°C for 15mins to eliminate any internal and external seed borne micro-organisms[8] (Ataga and Umechuruba,1997). After autoclaving the flasks were allowed to cool and 20ml of sterile distilled water was added to each flask and shaken gently to wet all the seeds, create humid and conducive environment. Each flask containing seeds was inoculated with a disc of 7 day old spores of each fungus of *Fusarium oxysporum* and *Macrophomina phaseolina* respectively obtained from the pure culture of isolated fungi from the infected seeds. This was carried out with a 1.5cm diameter sterile cork borer.

The flasks were gently shaken for about 15minutes to obtain uniform distribution of the mycelium among the seeds. The control flask, received the same treatment, but there was no fungi added to it. The entire flasks which include the fungi inoculated and uninoculated seeds were incubated at room temperature for 7days. At the end of the incubation period, two flasks of each fungal treatment and one flask for control were harvested for biochemical analysis. The seeds in each flask were transferred into a pre-weighed watch glass, dried at 45°C for 24 hours and the spores and mycelia of the fungi removed by sieving [8](Ataga and Umechuruba, 1997).

2.3 Determination of Crude Protein by Kjeldahl Method

The protein analysis was determined by kjeldahl nitrogen method described by [9] Osborne and Voogt (1978). The stages are Digestion, Distillation and Titration

2.3.1 Digestion

Into 250ml conical flask, 0.1g sample of inoculated and uninoculated seeds and 3g digestion catalyst were placed and 20mls concentrated sulphuric acid was added. The flask was heated to digest the content from black to sky-blue colouration. The digest was cooled to room temperature and was diluted to 100mls with distilled water.

2.3.2 Distillation

20ml diluted digest was measured into a distillation flask and the flask was held in place on an electro-thermal heater hot plate. It was then attached to a liebig condenser, connected to a receiver adaptor containing 10mls of 2% boric acid indicator. 40ml of 40% sodium hydroxide was injected into the digest via a syringe attached to the arm of the mimo arm steel head until the digest became strongly alkaline. The mixture was heated to boil and the ammonia gas was collected via the condenser into the receiver beaker. The color of the boric acid changed from purple to greenish as ammonia distillate was introduced into the boric acid.

2.3.3 Titration

The distillate was titrated with 0.1N Hydrochloric acid back to purple from greenish. The volume of Hydrochloric acid added to effect this change was recorded as the titre value.

\[
N_2 = \frac{\text{titre value} \times 1.4 \times 100}{1000 \times \text{weight of sample} \times \text{volume}}
\]

\%

\text{Crude protein} = \% N_2 \times \text{Conversion factor (F)}

Where\text{N}_2 = \text{Crude Nitrogen}, \text{F}=6.25

2.4 Determination of amino acid content amino acid extraction

Modified AOAC Method 982.30, 2006 was followed in the extraction of the sample for the amino acid analysis. The dried and pulverized sample was made to be free of water by ensuring constant weight for a period of time in the laboratory the sample of 10.0g was weighed into the 250ml conical flask capacity. The sample was defatted by extracting the fat content of the sample with 30ml of the petroleum spirit three times with
soxhlet that was equipped with thimble. The sample was hydrolyzed three times for complete hydrolysis to be achieved.

The amino acid content of the sample was recovered by extracting with 30ml of the dichloro methane three times before concentrating to 0.1ml. the concentrated extract was derivatised for volatility that is suitable for gas chromatography analysis.

2.4.1 Gas Chromatography Conditions for Amino Acids

GC: HP 6890 Powered with HP ChemoStation Rev. A 09.01 [1206] software
Injection Temperature: Split Injection
Carrier Gas: Hydrogen
Flow Rate: 1.0ml/min
Inlet Temperature: 250°C
Column Type: HP 5
Column Dimensions: 30m x 0.25mm x 0.25µm
Oven program: Initial @60°C
First Ramp @ 8°C/min for 20min, maintained for 2min.
Second Ramp @ 12°C/min for 6mins, constant for 2mins
Detector: PFPD
Detector Temperature: 320°C
Hydrogen Pressure: 20psi
Compressed Air: 35psi

III. Results

The results of the total amino acids of the fungi inoculated and uninoculated control *Jatropha curcas* seeds are presented in “Fig 1”. There was significant reduction (P=0.05) in total amino acids of seeds inoculated with *Fusarium oxysporum* (91.59g/100g protein) and *Macrophomina phaseolina* (90.41g/100g protein) compared to uninoculated control (93.23g/100g protein). The amino acid composition of the infected and uninfecte Jatropha seeds are presented in Table 1.

IV. Discussion

In this study, the fungi, caused increases in protein when compared to the control. The significant increase (P=0.05) in protein content by Fusarium oxysporum and Macrophomina phaseolina could have resulted from slight protein synthesis of enzyme proteins or other constituents[10] (Kuo et al., 1995). Also the report of Burnett [11](1976) explained that the formation of proteases by molds during fermentation may result in increased protein amino acids. This result agrees with the report of [12] Nwaukwu and Ataga,(2012) on the “Biological changes in Hibiscus sabdariffa (Yakwa) seed induced by Aspergillus niger, Aspergillus flavus, Fusarium oxysporum, Penicillium chrysogenum and Penicillium rouqueforti. The two fungi had an effect on the amino acid component of the seed residue (Table 1).

There was significant reductions in amino acid contents in residue from seeds inoculated with F. oxysporum and Macrophomina phaseolina when compared to the uninoculated seeds. Eight (8) essential amino acids and nine (9) nonessential amino acids were analyzed with inoculated and uninoculated. Pp. 220-72

These result indicate that these fungi cause seed deterioration in altering the nutritional value and quality of increased the crude protein and altered the amount of total amino acid as compared to the uninoculated seeds.

The analysis of nutrient in foods. Academic Press, London 159

The growth of Jatropha curcas increased the crude protein and altered the amount of total amino acid as compared to the uninoculated seeds. These result indicate that these fungi cause seed deterioration in altering the nutritional value and quality of Physic nut seeds.

V. Conclusion

From this study, the growth of F. oxysporum and M. phaseolina on the seeds of Jatropha curcas increased the amino acid content of and protein content of Jatropha Curcas Induced By Fusarium...
