**Abstract:** The present study was conducted for estimation of metabolites and enzymes of *Pongamiapinnata* abiodiesel plant of great economic importance. The hypertrophy and hyperplasia of plant tissues result in the formation of galls in some plants. *Pongamiapinnata* has leaves galls induced by *Aceriapongamiae*. Biochemical analysis revealed hyperauxiny and hypoindole 3 acetic acid oxidase activity in the gall tissues.

**Keywords:** *Pongamiapinnata*, biodiesel, gall, invertase, auxin, chlorophyll, carotenoid, enzymes

## I. Introduction

In order to address the shortages of feedstock for the production of biodiesel, new non-edible oil sources need to be exploited (Lin *et al*., 2011; Mustafa, 2011). Over hundred plant species are known to produce fatty acid oil. Among the oil bearing tree, *Pongamiapinnata* (family Fabaceae) also known as “Karanja” in India, appears to be a potential source of biodiesel (Sharma and Singh, 2008; Naik *et al*., 2008; Nabiet *et al*., 2009). It is medium sized glabrous evergreen tree with short bole attaining height of around 18-20 meter and its habitat is in the littoral region of south east Asia, Australia and widely distributed in India, Pakistan, Bangladesh, Philippine and Australia. This multipurpose tree has lot of industrial and medicinal applications. It is the one of the most extensively chemically investigated plant. Many gallers destroy plant parts with obvious links to host fitness, and compete with plant organs for nutrients and photosynthate and reduce it’s economically importance. *Aceriapongamiae* (Acarina: Eriophyidae) that induce pouch galls on the leaves of *Pongamiapinnata*. *A. pongamiae* synchronizes its development with the host phenology and it confirms the fact that life-history patterns of gall midges are closely linked to their host-plant phenology (Parnell, 1964; Tokuda and Yukawa, 2007).

## II. Materials And Methods

Normal and galled *Pongamiapinnata* leaves of equal size were collected from KeolaDeo National park, Bharatpur, Rajasthan and their biochemical study was done. The biochemical parameters were studied in normal and galled leaves at different ages (10days, 20days and old). The plant leaves (normal and galled) were separately washed with running water to remove dust and powdered with motor and pestle.

The quantitative estimation of primary metabolites was carried out using different protocols. The powdered plant leaves (normal and galled) and were used for estimation of IAA oxidase and total auxin content. The auxin contents were estimated by the method of Avery *et al*.(1945), invertase activity (Harris and Jaffcoat, 1974), chlorophylls (Arnon, 1949), carotenoid (Mahadevan and Sridhar, 1982) and lipid (Jayaraman, 1981) respectively.

The present work incorporates the biochemical estimation of some metabolites and enzymes of normal and galled leaves of *Pongamiapinnata* at different ages.

## III. Results And Discussion

The results are presented in table 1 and Fig. -1 to 7.

Plants are rich sources of primary metabolites which are useful in flavoring, fragrances, insecticides, sweeteners and natural dyes (Kaufman *et al*., 1999). Primary metabolites analysis is necessary for knowing the nutritional potential of plants and them also from the precursors for the synthesis of secondary metabolites (Vijayvergia and Kumar, 2007).

Higher amount of free auxin content and IAA oxidase was found in the gall tissue as compared to normal tissue. Higher levels of auxin will cause cell expansion (hypertrophy) and cell division (hyperplasia) in many plants (Sachs, 1961; Jablonski and Skoog, 1954; Nitsch, 1968). In old gall the number of infected larva is reduced. Indole-3-acetic acid (IAA), the main auxin in higher plants, has profound effects on plant growth and development. Both plants and some plant pathogens can produce IAA to modulate plant growth (Zhao, 2010). Although most investigations report hyperauxiny in galls, in a few cases reduced auxin levels has been reported (Raman and Kant, 1989). The amount of total auxin was reduced may be due to destruction by enzymes secreted by the parasite/insect or by enzyme of the infected plant or reduced concentration and conversion of auxin precursors (Gupta, 2011).
Invertase activity was recorded to be more in gall tissue as compared to normal tissues. Invertases are key metabolic enzymes that involved in various aspects of the plant life cycle and alone or in combination with plant hormones, can regulate many aspect of the growth and development of plants.

Highest amount of total chlorophyll and carotenoid was recorded in normal tissue as compared to gall tissues (10days, 20days and old). Chlorophyll is the most indispensable class of primary compounds as they are the only substances that capture sunlight and make it available to plant system for its cultivation on photosynthesis (Murray et al., 1986). The decrease in the photosynthetic pigments may be due to the inhibition of pigment biosynthesis which may results from the alteration in mineral nutrition or lack of assimilates which drain towards the insect or to the effect of reactive oxygen species on these pigments (Stacey and Keen, 1996). Degradation of chlorophylls compounds in aphid induced galls has earlier been reported by Miles (1968) and Purohit (1979). There are over 600 known carotenoids; they are split into two classes, xanthophylls (which contain oxygen) and carotenes (which are purely hydrocarbons, and contain no oxygen). Carotenoids in general absorb blue light. They serve two key roles in plants and algae: they absorb light energy for use in photosynthesis, and they protect chlorophyll from photodamage (Armstrong and Hearst, 1996).

Lipid was recorded to be more in normal tissue as compared to gall tissues (10 days, 20 days and old). Plants protect themselves from herb ivory by the formation of a layer of lipid material called thick cuticle (a waxy outer layer) which reduce water loss and work as a defense against some insects (Taiz and Zeiger, 1998). Lipid a diverse group of primary metabolites, include reserve plant material such as fats, essential oils, waxes terpenoids and oleoresin. Plant lipid have developed products that work with diverse requirements, be it culinary, medicinal or cosmetic (Yadav and Tyagi, 2006).

The majority of lipids in biological systems function either as a source of stored metabolic energy or as structural matrices and permeability barriers in biological membranes. Very small amounts of special lipids act as both intracellular messengers and extracellular messengers such as hormones and pheromones.

IV. Conclusion

The present study revealed the nature of metabolites and enzymes that are depleted from leaf tissue during gall formation as a consequence of the invasion of the parasite. The reduction in the metabolites and enzymes mentioned in the results in the galls may be a case of deficiency thus increasing the susceptibility of the plant to insect parasite.
