Abstract: The spectral properties (absorption and fluorescence) of Rhodamine B dye have been studied. This type of dye belong to the Xanthenes family and it was dissolved in chloroform with different concentrations (3×10⁻⁵, 8×10⁻⁵, 8×10⁻⁴, 5×10⁻⁴, 2×10⁻³ and 2×10⁻³ mole/liter) at room temperature. The achieved results have been pointed out there are a blue shift in the absorption spectra and red shift in the fluorescence spectra as the concentration increased. The quantum efficiency of the dissolved RB in chloroform were (53%, 58%, 67%, 76%, 78% and 89%) for the above concentrations respectively. It has been noticed that the quantum efficiency decreased as a function of concentration. There is a good consistency of the behavior of the fluorescence and absorption spectra with Beer.

Keywords: Fluorescence, Absorbance, Rhodamine B, Quantum efficiency.

I. Introduction:
Laser dyes can usually be used for a much wider range of wavelengths. The wide bandwidth makes them particularly suitable for tunable lasers and pulsed lasers. Moreover, the dye can be replaced by another type in order to generate different wavelengths with the same laser, although this usually requires replacing other optical components in the laser as well. Dye lasers were independently discovered by P. P. Sorokin and F. P. Schäfer (and colleagues) in 1966[1, 2]. In addition to the usual liquid state, dye lasers are also available as solid state dye lasers (SSDL). SSDL use dye-doped organic matrices as gain medium[3-10].

Many studies focused on Xanthenes family which Rodamine B belong to them because of there higher gain[11, 12] and their properties differ with many parameters (like, different solvents, different concentrations,...). The chemical structure of RhodamineBis shown in Figure (1).

Theoretical Consideration
The spectrum of the molecular fluorescence \( F(\nu) \) gives the relative fluorescence intensity at wave-number \( \nu \), this is related to the quantum efficiency by the following equation ,[14].

\[
q_{\text{fm}} = \int_{0}^{\infty} F(\nu')d\nu'
\]

In order to evaluate absolute quantum efficiency, we have to consider both the radiative and non-radiative processes taking place in the medium, therefore

\[
q_{\text{a}} = \frac{K_{\text{ISC}}}{K_{\text{ISC}} + \Sigma K_{d}} = \frac{K_{\text{ ISC}}}{K_{\text{ ISC}} + K_{\text{ IC}} + K_{\text{ IC}}} \]

\[
\text{--- (2)}
\]
Since \( K_{fm} = 1/\tau_{fm} \) and \( \tau_{f} = 1 / K_{fm} + \sum K_d \)

Therefore

\[
q_{fn} = \frac{\tau_f}{\tau_{fm}} = \int_{0}^{\infty} F(\nu')\,d\nu'
\]

----- (3)

Also

\[
q_{fm} = \frac{\text{Number of quanta emitted}}{\text{Number of quanta absorbed}}
\]

where

\( \tau_{fm} \): The radiation life time can be calculated using relation as follow

\[
\frac{1}{\tau_{FM}} = 2.88 \times 10^{-9} n^2 (\nu')^2 \int c(\nu) d\nu'.
\]

----- (4)

Where

\( n \): refractive index of a medium
\( \nu' \): wave number at the maximum absorption
\( \int c(\nu) d\nu' \): the area under the absorption spectrum curve as a function of the wavenumber. [15]

**Experimental Work:**

**The materials used in search**

The molecular formula of the RB is \( \text{C}_28\text{H}_31\text{N}_2\text{O}_3 \)Cland processed by the company (HIMEDIA) India. This character belongs to the Xanthenes family and the molecular weight is 479.02 gm/mol.

**The solvent (Chloroform)**

Chloroform is the organic compound with formula \( \text{CHCl}_3 \). The colorless, sweet-smelling, dense liquid is a trihalomethane, and. The physical properties as shown in the table.

![Chloroform Structure](image)

Chloroform Structure, [16].

**Instrument used in work:**

- Fluorescence spectrum was measured by a (Spectrofluorometer SL174) by the processor (Elico)
- Absorption spectrum was measured by a (SP-8001.UV-visible spectrophotometer) by the processor (MetertechInc)

The preparation of dye solution with different concentration was taken place by dissolving an appropriate amount of dyepowder in a given volume of solvent used, according to the relationship:

\[
W = \frac{M_w VC}{1000} \quad ----- (5)
\]

Where

\( W \): Weight of the dissolved dye (gm)
\( M_w \): Molecular weight of the dye (gm/mol)
\( V \): The volume of the solvent (ml)
\( C \): The dye concentration (mol/l)
The prepared solutions were diluted according to the following equation:
\[ C_1 V_1 = C_2 V_2 \]

Where:
- \( C_1 \): primary concentration
- \( C_2 \): new concentration
- \( V_1 \): the volume before dilution
- \( V_2 \): the volume after dilution

II. Results and Discussion

During the study of the spectral properties of the Rhodamine B dissolved in the chloroform solvent, the following results can be deduced. Figures (2-7) show the absorption and fluorescence spectra of the solution with different concentrations \( 3 \times 10^{-5}, 8 \times 10^{-5}, 8 \times 10^{-4}, 5 \times 10^{-4}, 2 \times 10^{-3} \) and \( 2 \times 10^{-3} \) mol/liter respectively. The maximum wavelength of the fluorescence and absorption spectra was shown to depend on the concentration of the dye solution, as shown in the figures. Table (1) shows the absorption, fluorescence peaks, and the quantum efficiency of the dye and Stokes Shift. At dilute of dye, \( 3 \times 10^{-5} \) mol/litre, the quantum efficiency appears high while the maximum wavelength shift (Stokes Shift) is 132 nm, the quantum yield of the dye solution decreases as the dye concentration increase, as shown in Figure (8). Increasing the concentration of the dye solution resulted in red shifting of the fluorescence wavelength to higher wavelengths.

III. Conclusion

From the observed results of studying the fluorescence and absorption spectra of Rhodamine B dye dissolved in chloroform one can conclude the following:

1. The increase in dye concentration showed an increase in relative intensity for both spectra, which is in agreement with Beer–Lambert law.
2. The Stock's shift for fluorescence spectrum of the RB dye dissolved in chloroform is toward the longer wavelength (low energy) as the concentration increased.
3. It must be noted that the quantum yield of the dye solution decreases as the dye concentration increase.
4. As the dye concentration increase the interference region between the fluorescence and absorption spectra have been increased which produced a decrease in Stock's shift.
