## Abstract

This study investigated the volatility of exchange rate and consumer price index in Nigeria using monthly series from 2010M1 to 2022M10. The GARCH (1,1) framework and a standard GARCH test in an ARIMA framework were used to check the volatility clustering. The Johansen System cointegration test and Block exogeneity test confirm a long run relationship degree and direction of causality between exchange rate volatility and consumer price volatility. Again, a long run cointegrating unidirectional causality running from consumer price index volatility to exchange rate volatility without feedback, was found. Further findings arising from the study showed that exchange rate and consumer price index exhibited volatility properties in the Nigerian economic environment. Also, a reasonably size correlational coefficient was documented which is connotative of a linear association between exchange rate volatility and price volatility. This study recommends wholistic and systembased approach to policy formulation given the likelihood of transmission effect from the volatility of consumer price index to exchange rate.

## I. Introduction

Following the collapse of the gold standard system in 1971, most countries abandoned fixed exchange rates for floating systems, which in turn lead to an increased volatility in exchange rates. Besides, transmission of various endogenous and exogenous economic shocks to macroeconomic variables has increased. Statistically, volatility is often regarded as variance and it is a measure of the dispersion of a random variable from its mean value. Thus, Exchange volatility relates to the fluctuations (or instability) in a chosen measure of foreign exchange or exchange rate (Omotosho & Doguwa 2012). Inflation volatility relates to the fluctuations (or instability) in a chosen measure of inflation. In Nigeria, for instance, monthly headline inflation is measured in terms of the year-on-year percentage change in the all-items Consumer Price Index (CPI) compiled by the National Bureau of Statistics (NBS) and fluctuations in such a measure characterizes inflation volatility in the country (Judson & Orphanides, 1999).

Globally, one of the key challenges to economic policy management all over the world and particularly in emerging and developing economies has been the effect of changes in exchange rates on inflation and economic activities. It is believed that exchange rate movements would create domestic economic distortions and affect a country's economic competitiveness. The deleterious effect of exchange rate misalignment is well documented in literature and there is often reluctance on the side of policy makers to adjust exchange rates due to perceived negative effect on the economy, mainly due to pass-through effects.

Similarly, one of the most serious challenges facing Nigeria and most developing economies is inflationary pressure coupled with exchange rate volatility. The adverse or consequences of inflationary pressure arising from exchange rate volatility have been a serious concern for financial economists, policy makers, and researchers. In Nigeria, the Central Bank is saddled with the responsibility of maintaining stable exchange rate and price stability in the economy and, this is done by ensuring that the rate of inflation is kept within a certain bound (Nuhu, 2021). Furthermore, the central bank maintains the stability of the Naira exchange rate in order to achieve its objective of maintaining price stability as domestic prices respond to exchange rate fluctuations.

According to Ubi, Effiom, and Eyo (2012), in countries where exchange rate volatility tends to have adverse effects on inflationary pressure, more stable exchange rate through central bank intervention in the foreign exchange market is required in order to stabilize the economy. The Central bank uses its monetary policy such as monetary policy rate, interest rate, open market operation, and other weapons to stabilize the economy with a view to achieving some specified macroeconomic policy objectives and to counter undesirable

trends in the economy such as unemployment, inflationary pressures, sluggish economic growth and external sector instability.

Literature has underscored the importance of exchange rate as a veritable tool for achieving overall economic progress. This is based on the link between exchange rate and other economic variables including inflation. The crucial role of exchange rate in monetary policy formulation is also emphasized, as it serves as an essential part of signaling channel of the transmission of policy decisions to achieve the desired macroeconomic objectives. It has therefore placed responsibility on this study to establish a clear relationship between volatility in exchange rate and volatility in inflation rate measured in Consumer Price Index. Hence, an in-depth understanding of the effect of exchange rate volatility on Consumers Price Index in Nigeria is essential for policy formulation and implementation.

## II. Theoretical framework

Various theories of exchange rate, monetary policy and inflation relate to this study. These include the classical theory, monetarist's theory, Keynesians theory and the Purchasing Power Parity. First, the classical theory or Quantity theory of money (QTM) propounded by Irving Fisher in 1956 postulates a direct and proportional relationship between money supply and the price level. That is, change in the supply of money causes a proportional change in the price level. Algebraically, it is expressed as follows: MV = PT 1 where: M is the total money supply, V is the velocity of money in circulation and T is the volume of transactions. From the equation, the total money supply (MV) equals total value of output (PT) in the economy. Assuming V (the velocity of money) and T (the total output) to be constant, a change in the supply of money (M) causes a proportional change in the price level. The variable M is the policy variable, which is exogenously determined by the monetary authorities (Nuhu, 2021).

Secondly, the monetarists led by Milton Friedman posit that money exerts significant influence on aggregate demand, price level and output (Ufoeze, et al 2018). The monetarists are of the view that changes in money supply determine the nominal price level and output. The Thirdly, Keynesian economic theory posit that expansionary monetary policy increases the supply of loanable funds available through banking system, causing interest rates to fall. With the lower interest rates, aggregate investment increases, causing real gross domestic product to rise (Chukwuemeka, 2018; Nwoko, Ihemeje, & Anumadu, 2016). Keynes contends that monetary policy affects real output indirectly. Keynes did not support the idea that the relationship between money and price is direct and proportional, rather Keynes contends that a change in the supply of money has an indirect and non-proportional relationship with economic variables such as interest rate, investment, aggregate demand, level of employment, output and income.

Fourthly, Mundell- Fleming Theory of Exchange rate determination on the other hand, is an extension of the IS-LM framework which deals with equilibrium in the product market and money market. In the Mundell-Fleming theory, the balance of payments is considered another equilibrium condition in addition to the product market and money market equilibrium. The Mundell-Fleming theory posits that expansionary monetary policy increases the supply of loanable funds available through banking system, causing interest rates to fall. The fall in interest rates leads to fall in capital inflows which results to capital account deficit leading to further pressure on domestic currency thereby causing depreciation of the exchange rate. The depreciation in currency stimulates domestic production causing IS curve and balance of payments (BP) curve to shift to the right (Chukwuemeka, 2018; Nwoko et al., 2016). The IS represents the investment and savings equilibrium in the product market while the LM represents the liquidity preference and money supply equilibrium in the money market (Nuhu, 2021)

Finally, the purchasing power parity (PPP) theory was developed by Swedish economist Gustav Cassel. This theory posits that the exchange rate between countries is determined by their relative price level. It explains how the exchange rate volatility affects inflation rates (Jhingan, 2011). This study is principally underpinned by the purchasing power parity theory.

## 2.2 Empirical review

Empirical literatures exist on the relationship between exchange rate volatility and Consumers Price Index in empirical works carried out in Nigeria and other countries. In Nigeria, Yakub et al. (2019) investigated the impact of exchange rate volatility on trade flows in Nigeria using annual time series data for the period 1997-2016. A GARCH model was used to generate the nominal exchange rate volatility series. To detect the long-run relationship among variables, the ARDL bounds test approach was employed. Also, the Granger causality test was applied to ascertain the direction of causality among the variables. The study found that exchange rate volatility affected Nigeria's trade flows negatively in the short-run but does not in the long-run.

Nkoro & Uko (2016) investigated the effect of exchange rate volatility on inflation in Nigeria, using quarterly time series data from 1986QI-2012Q4 sourced from the CBN Statistical Bulletin and National Bureau of Statistics. The study employed GARCH model. Findings from the study revealed a persistent volatility in

exchange rate and inflation rate in the Nigeria. Obiekwe and Osabunhien (2016) examined the effect of exchange rate volatility on inflation in Nigeria using annual time series data from 2006 to 2015. The study employed the GARCH technique to test for volatility in exchange rate in Nigeria. The study applied the ARCH model in its analysis. The result revealed that volatility in exchange rate significantly influenced inflation rate in Nigeria.

Besides, Ajao and Igbekoyi (2013) investigated the determinants of real exchange rate volatility in Nigeria using annual time series data from 1981 to 2008. Using Generalized Auto-regressive Conditional Heteroskedasticity (GARCH) techniques and the Error Correction Model (ECM). The results revealed that trade openness, government expenditures, interest rate and the lagged exchange rate had positive and significant effect on real exchange rate volatility during the period under investigation.

Similarly, Dickson and Andrew (2013) analyzed the impact of exchange rate fluctuations on trade variations in Nigeria for the period 1970 - 2010. The study employed the error correction and GARCH model for the analysis and results of the study showed that exchange rate volatility was not significant in explaining variations in import, but was found to be positive and significant in accounting for variations in export. Joseph (2011) investigated the impact of real exchange rate volatility on economic growth in Nigeria from 1970-2009. The study used the GARCH model for the analysis. Results indicated that a negative and insignificant transmission existed between exchange rate volatility and economic growth. Aliyu (2010) analysed the impact of exchange rate volatility on Nigeria's non-oil exports using quarterly data from 1986 - 2006. Using vector error correction and the VAR model. The results revealed a long-run stable and negative relationship between Naira exchange rate and non-oil exports in Nigeria.

Reviewing empirical works from other countries or cross countries analyses have some variations. Achouak, Ousama, and Mourad (2018) examined the impact of exchange rate volatility on economic growth in a sample of 45 developing and emerging countries over the period 1985-2015. The study employed generalized autoregressive conditional heteroskedasticity (GARCH) model for the analysis. Findings revealed that nominal and real exchange rate volatilities had negative and significant impact on economic growth. In a study on the effect of exchange rate volatility on inflation in Switzerland using Structural Vector Auto regressive (SVAR) technique, Zidek and Suterova (2017) found that exchange rate volatility caused inflationary pressure in the study area. On their part, Viola, et al (2017) explored the effect of exchange rate volatility on inflation in Brazil using annual time series data from 1980-2015 sourced from Central Bank of Brazil. Findings from the study revealed that GARCH (1,1) and the EGARCH (1,1) showed high persistence of volatility in the exchange rate.

Also, Serenis and Tsounis (2014) investigated the effect of exchange rate volatility on two small countries, Croatia and Cyprus on aggregate exports using annual time series data for the period 1990 to 2012. Autoregressive distributed lag (ARDL) model was employed for the analysis and results revealed a positive and significant effect of exchange rate volatility on exports of Croatia and Cyprus. Vieira, et al (2013) analysed the impact of exchange rate volatility on economic growth on a sample of 82 developed and emerging countries over the period of 1970-2009. The study employed generalized autoregressive conditional heteroskedasticity (GARCH) model for the analysis. Findings revealed that nominal and real exchange rate volatilities had negative and significant impact on economic growth in the sampled countries.

Besides, Mori, et al (2012) investigated the effects of the exchange rate volatility on economic growth in Malaysia during the period 1971- 2009. The variables employed include; GDP, real exchange rate and nominal exchange rate. The study employed Autoregressive Distributed Lag approach for the analysis. Results revealed that both nominal and real exchange rates had a positive and significant effect on economic growth in Malaysia.

From the literature reviewed, it is clear that studies that examined the relationship between exchange rate volatility and Consumer Price Index (CPI) in Nigeria were few. This study is one of few studies that would examine the impact of exchange rate volatility on Consumer Price Index in Nigeria, particularly using the ARDL approach. This study will contribute to the existing literature in terms of methodology used and variables employed in the study.

## III. Methodology

3.1 Data and Method

The data for this study are extracted from the Central Bank statistical bulletin covering the period 2010M1 to 2022M10. It is a monthly series given the fact that high frequency data like monthly data are efficient in measuring volatility.

# First, the collected data were described using basic descriptive statistics, test for correlation, graphs and descriptive charts. Prior to the description, the volatility profile of the datasets was shown using a GARCH (1,1) model as:

$$Y_{t} = X_{t}^{'}\theta + \epsilon_{t} \qquad \qquad \text{eqn (1)}$$
  
$$\sigma_{t}^{2} = \omega + \alpha \epsilon_{t-1}^{2} + \beta \sigma_{t-1}^{2} \qquad \qquad \qquad \text{eqn (2)}$$

Where:

The mean equation given in eqn (1) is written as a function of exogenous variables with an error term. Since is the one-period ahead forecast variance based on past information, it is called the *conditional variance*. The conditional variance equation specified in eqn (2) is a function of three terms:

• A constant term:  $\omega$  News about volatility from the previous period, measured as the lag of the squared residual

from the mean equation:  $\varepsilon_{t-1}^2$  (the ARCH term). Last period's forecast variance:  $\sigma_{t-1}^2$  (the GARCH term). The (1, 1) in GARCH (1, 1) refers to the presence of a first-order autoregressive GARCH term (the first term in parentheses) and a first-order moving average ARCH term (the second term in parentheses). The conditional variance residual series of the volatile variables are identified as the series for the measurement of volatility for both CPI and Exchange Rate.

Second, the graph of the residual series as well as their test for heteroscedasticity were used to confirm their volatility properties which is the first objective of this study. Evidently, a graph that shows periods of low volatility succeeded the period of low volatility and high volatility going along the same line form empirical evidence of existence of volatility clustering.

Third, the volatility series and other moderating variables are used to determine the long run cointegrating relationship of the series in a Johansen type cointegrating system equation. Also, the block exogeneity test is used to measure the direct and reverse causal interaction among the variables under investigation. All inferences were based on the 0.05 level of significance.

4.2: A presentation of a graph of the level series of the CPI and EXR were firstly presented as Fig.1 and Fig.2 Log Differenced CPI

There is an observance of oscillatory movement in the CPI series but this is not conclusive evidence as the GARCH residual series tests provide a confirmatory support to the initial observations.

Fig. 2 – Log Differenced Line Graph of Monthly USD to Naira EXR series, 2010M1 to 2022M10

Following the GARCH (1,1) process described on section 3, the residual series are extracted and graphed of the form shown in Fig. 3 and Fig. 4.

| It is concluded that CPI and EXR in the Nigerian economic space exhibited clear-cut volatility over the period  |

## Table 1: GARCH Test Results for CPI and EXR

Source: Authors' Computation

The sum of the ARCH and GARCH terms are close to unity (1) in both the CPI and EXR. Also, the reported coefficient was significant at the 0.05 level of significance. This is clearly a proof of strong volatility in exchange rate and consumer price index in Nigeria over the studied period.

Next, having established the volatility status of the series, the basic descriptive statistics are reported in table 2.

## Table 2: Summary of Basic Descriptive Statistics

## Source: Authors' Computation

A comparism of the averages of the level series and the log transformed series provided justification for the use of the log transformed series in reducing data magnitude while ensuring linearity. All the variables become close-knit with reduced deviation around the mean when the log transformed series were used. The results further showed the linear association of the series by revealing the correlation matrix as reported in table 3.

|         | CPI      | LCPI     | LUSDEXR  | USDEXR   |
|---------|----------|----------|----------|----------|
| LCPI    | 0.981041 | 1.000000 |          |          |

## Source: Authors' Computation

Positively significant correlation was found among all the investigated variables. The correlation coefficient that were appreciably high. And all the t-stats found to be significant at the 0.05 level of significance. This suggest positive comovement between EXR and CPI in the Nigerian economic space.

The possible cointegrating relationship between inflation and exchange rate was investigated and reported in table 4.2

 Table 4: Cointegration Rank Test (Trace)

#### Source: Authors' Computation

The trace test and maximum Eigen value test both confirm the existence of cointegration with the trace test reporting three cointegrating vectors and the Maxeigen statistics showing two cointegrating vectors. Summarily, it was found that exchange rate and consumer price index in Nigeria share a long run relationship. Lastly, the direction of direction of the causal movement between exchange rate and consumer price index was shown in the block exogeneity tests reported from a Vector Error Correction framework as shown in table 5.

| Table 5: VEC Granger | Causality/Block Exogeneity | Wald Tests |

## Source: Authors' Computation

Though all the variables showed block causality for the consumer price index volatility as well as exchange rate volatility, the study only found a unidirectional causality between exchange rate volatility and consumer price index volatility. The causality runs from consumer price index volatility to exchange rate volatility without feedback. This implies that the exchange rate volatility responded to the volatility of domestic inflation than exchange rate responds to the volatility of inflation.

## V. Conclusions and Implications of the Study

This study examined the likelihood of volatility clustering in exchange rate and consumer price index in Nigeria using monthly series from 2010M1 to 2022M10. The volatility series were extracted using a GARCH (1,1) framework and a standard GARCH test in an ARIMA framework was conducted. Long run relationship was confirmed using the Johansen System cointegration test and Block exogeneity test used to determine the degree and direction of causality between exchange rate volatility and consumer price volatility. It is concluded that exchange rate and consumer price index exhibit volatility properties in the Nigerian economic environment. Also, a reasonably size correlational coefficient is documented which is connotative of a linear association between exchange rate volatility and price volatility. The Johansen's trace test and maxeigen value are in agreement as to the existence of a long run cointegrating relationship between exchange rate and consumer price index volatility. A unidirectional causality running from consumer price index volatility to exchange rate volatility without feedback, was found. This study recommended the need for a wholistic and system-based approach to policy formulation given the observed likelihood of transmission and spillover effect from the volatility of consumer price index to exchange rate. Also, exchange rate and inflation are among the key issues that monetary policy addresses in most economies including Nigeria; hence, the need for a balanced and allinclusive monetary policy approach is emphasized by the outcome of this investigation.
