#### Abstract

In this paper, an analysis is presented to find the numerical solutions of the second order linear and nonlinear differential equations with Robin, Neumann, Cauchy and Dirichlet boundary conditions. We use the Legendre piecewise polynomials to the approximate solutions of second order boundary value problems. Here the Legendre polynomials over the interval [ 0,1 ] are chosen as trial functions to satisfy the corresponding homogeneous form of the Dirichlet boundary conditions in the Galerkin weighted residual method. In addition to that the given differential equation over arbitrary finite domain $[a, b]$ and the boundary conditions are converted into its equivalent form over the interval [0,1]. Numerical examples are considered to verify the effectiveness of the derivations. The numerical solutions in this study are compared with the exact solutions and also with the solutions of the existing methods. A reliable good accuracy is obtained in all cases.

Keywords: Galerkin Method, Linear and Nonlinear VBP, Legendre polynomials

## I. Introduction

In order to find out the numerical solutions of many linear and nonlinear problems in science and engineering, namely second order differential equations, we have seen that there are many methods to solve analytically but a few methods for solving numerically with various types of boundary conditions. In the literature of numerical analysis solving a second order boundary value problem of differential equations, many authors have attempted to obtain higher accuracy rapidly by using numerical methods. Among various numerical techniques, finite difference method has been widely used but it takes more computational costs to get higher accuracy. In this method, a large number of parameters are required and it can not be used to evaluate the value of the desired points between two grid points. For this reason, Galerkin weighted residual method is widely used to find the approximate solutions to any point in the domain of the problem.

Continuous or piecewise polynomials are incredibly useful as mathematical tools since they are precisely defined and can be differentiated and integrated easily. They can be approximated any function to any accuracy desired [1], spline functions have been studied extensively in [2-9]. Solving boundary value problems only with Dirichlet boundary conditions has been attempted in [4] while Bernstein polynomials [10, 11] have been used to solve the two point boundary value problems very recently by the authors Bhatti and Bracken [1] rigorously by the Galerkin method. But it is limited to the second order boundary value problems with Dirichlet boundary conditions and to first order nonlinear differential equation. On the other hand, Ramadan et al. [2] has studied linear boundary value problems with Neumann boundary conditions using quadratic cubic polynomial splines and nonpolynomial splines. We have also found that the linear boundary value problems with Robin boundary conditions have been solved using finite difference method [12] and Sinc-Collocation method [13], respectively. Thus except [9], little concentration has been given to solve the second order nonlinear boundary value problems with dirichlet, Neumann and Robin boundary conditions. Therefore, the aim of this paper is to present the Galerkin weighted residual method to solve both linear and nonlinear second order boundary value problems with all types of boundary conditions. But none has attempted, to the knowledge of the present authors, using these polynomials to solve the second order boundary value problems. Thus in this paper, we have given our attention to solve some linear and nonlinear boundary value problems numerically with different types of boundary conditions though it is originated in [1].

However, in this paper, we have solved second order differential equations with various types of boundary conditions numerically by the technique of very well-known Galerkin method [15] and Legendre piecewise polynomials [14] are used as trial function in the basis. Individual formulas for each boundary value problem consisting of Dirichlet, Neumann, Robin and Cauchy boundary conditions are derived respectively. Numerical examples of both linear and nonlinear boundary value problems are considered to verify the effectiveness of the derived formulas and are also compared with the exact solutions. All derivations are performed by MATLAB programming language.

## II. Legendre Polynomials

The solution of the Legendre's equation is called the Legendre polynomial of degree $n$ and is denoted by $p_{n}(x)$.
Then $p_{n}(x)=\sum_{r=0}^{N}(-1)^{r} \frac{(2 n-2 r)!}{2^{n} r!(n-r)!(n-2 r)!} x^{n-2 r}$
where $N=\frac{n}{2} \quad$ for n even
and $N=\frac{n-1}{2} \quad$ for n odd
The first few Legendre polynomials are

$$
\begin{aligned}
& p_{1}(x)=x \\
& p_{2}(x)=\frac{1}{2}\left(3 x^{2}-1\right) \\
& p_{3}(x)=\frac{1}{2}\left(5 x^{3}-3 x\right) \\
& p_{4}(x)=\frac{1}{8}\left(35 x^{4}-30 x^{2}+3\right) \\
& p_{5}(x)=\frac{1}{8}\left(63 x^{5}-70 x^{3}+15 x\right) \\
& p_{6}(x)=\frac{1}{16}\left(231 x^{6}-315 x^{4}+105 x^{2}-5\right) \\
& p_{7}=\frac{1}{16}\left(429 x^{7}-693 x^{5}+315 x^{3}-35 x\right) \text { etc }
\end{aligned}
$$

## Graphs of first few Legendre polynomials

## Shifted Legendre polynomials

Here the "shifting" function (in fact, it is an affine transformation) is chosen such that it bijectively maps the interval $[0,1]$ to the interval $[-1,1]$, implying that the polynomials are
An explicit expression for the shifted Legendre polynomials is given by orthogonal on $[0,1]$ :

$$
\tilde{p}(x)=(-1)^{n} \sum_{k=0}^{n}\binom{n}{k}\binom{n+k}{k}(-x)^{k}
$$

The analogue of Rodrigues' formula for the shifted Legendre polynomials is

$$
\tilde{p}(x)=\frac{1}{n!} \frac{d^{n}}{d x^{n}}\left(x^{2}-x\right)^{n}
$$

To satisfy the condition $p_{n}(0)=p_{n}(1)=0, n \geq 1$, we modified the shifted Legendre polynomials given above in the following form

$$
p_{n}(x)=\left[\frac{1}{n!} \frac{d^{n}}{d x^{n}}\left(x^{2}-x\right)^{n}-(-1)^{n}\right] \times(x-1)
$$

Since Legendre polynomials have special properties at $x=0$ and $x=1: \quad p_{n}(0)=0$ and $p_{n}(1)=0, n \geq 1$ respectively, so that they can be used as set of basis function to satisfy the corresponding homogeneous form of the Dirichlet boundary conditions to derive the matrix formulation of second order BVP over the interval $[0,1]$.

## III. Formulation Of Second Order Bvp

We consider the general second order linear BVP [15]:
$-\frac{d}{d x}\left(p(x) \frac{d u}{d x}\right)+q(x) u=r(x), \quad a<x<b$
$\alpha_{0} u(a)+\alpha_{1} u^{\prime}(a)=c_{1}, \beta_{0} u(b)+\beta_{1} u^{\prime}(b)=c_{2}$
where $p(x), q(x)$ and $r$ are specified continuous functions and $\alpha_{0}, \alpha_{1}, \beta_{0}, \beta_{1}, c_{1}, c_{2}$ are specified numbers. Since our aim is to use the Legendre polynomials as trial functions which are derived over the interval $[0,1]$, so the BVP (1) is to be converted to an equivalent problem on [ 0,1$]$ by replacing x by $(b-a) x+a$, and thus we have:
$-\frac{d}{d x}\left(\tilde{p}(x) \frac{d u}{d x}\right)+\tilde{q}(x) u=r(x), 0<x<1$
$\alpha_{0} u(0)+\frac{\alpha_{1}}{b-a} u^{\prime}(0)=c_{1}, \beta_{0} u(1)+\frac{\beta_{1}}{b-a} u^{\prime}(1)=c_{2}$
where $\tilde{p}(x)=\frac{1}{(b-a)^{2}} p((b-a) x+a), \quad \tilde{q}(x)=q((b-a) x+a), \tilde{r}(x)=r((b-a) x+a)$
Using Legendre polynomials, $p_{i}(x)$ we assume an approximate solution in a form,

$$
\begin{equation*}
\tilde{u}(x)=\sum_{i=1}^{n} a_{i} p_{i}(x), \quad n \geq 1 \tag{3}
\end{equation*}
$$

Now the Galerkin weighted residual equations corresponding to the differential equation (1a) is given by
$\int_{0}^{1}\left[-\frac{d}{d x}\left(\tilde{p}(x) \frac{d \tilde{u}}{d x}\right)+\tilde{q}(x) \tilde{u}-\tilde{r}(x)\right] p_{j}(x) d x=0, j=1,2, \ldots, n$
After minor simplification, from (2) we can obtain

$$
\begin{align*}
& \sum_{i=0}^{n}\left[\int_{0}^{1}\left[\tilde{p}(x) \frac{d p_{i}}{d x} \frac{d p_{j}}{d x}+\tilde{q}(x) p_{i}(x) p_{j}(x)\right] d x+\frac{\beta_{0}(b-a) \tilde{p}(1) p_{i}(1) p_{j}(1)}{\beta_{1}}-\frac{\alpha_{0}(b-a) \tilde{p}(0) p_{i}(0) p_{j}(0)}{\alpha_{1}}\right] a_{i} \\
& =\int_{0}^{1} \tilde{r}(x) p_{j}(x) d x+\frac{c_{2}(b-a) \tilde{p}(1) p_{j}(1)}{\beta_{1}}-\frac{c_{1}(b-a) \tilde{p}(0) p_{j}(0)}{\alpha_{1}} \tag{5}
\end{align*}
$$

Or, equivalently in matrix form

$$
\begin{gather*}
\sum_{i-1}^{n} K_{i, j} a_{i}=F_{j}, \quad j=1,2,3, \cdots \cdots \cdots, n  \tag{6a}\\
\text { where } K_{i, j}=\int_{0}^{1}\left[\tilde{p}(x) \frac{d p_{i}}{d x} \frac{d p_{j}}{d x}+\tilde{q}(x) p_{i}(x) p_{j}(x)\right] d x+\frac{\beta_{0}(b-a) \tilde{p}(1) p_{i}(1) p_{j}(1)}{\beta_{1}}-\frac{\alpha_{0}(b-a) \tilde{p}(0) p_{i}(0) p_{j}(0)}{\alpha_{1}}  \tag{6b}\\
F_{j}=\int_{0}^{1} \tilde{r}(x) p_{j}(x) d x+\frac{c_{2}(b-a) \tilde{p}(1) p_{j}(1)}{\beta_{1}}-\frac{c_{1}(b-a) \tilde{p}(0) p_{j}(0)}{\alpha_{1}}, j=1,2, \cdots, n \tag{6c}
\end{gather*}
$$

Solving the system (6a), we find the values of the parameters $a_{i}(i=1,2, \ldots, n)$ and then substituting these parameters into eqn. (3), we get the approximate solution of the boundary value problem (2). If we replace $x$ by $\frac{x-a}{b-a}$ in $\tilde{u}(x)$, then we get the desired approximate solution of the boundary value problem (1).
Now we discuss the different types of boundary value problems using various types of boundary conditions as follows:
Case 1: The matrix formulation with the Robin boundary conditions $\left(\alpha_{0} \neq 0, \alpha_{1} \neq 0, \beta_{0} \neq 0\right.$, $\beta_{1} \neq 0$ ), are already discussed in equation (6).
Case 2: The matrix formulation of the differential equation (1a) with the Dirichlet boundary conditions (i.e., $\alpha_{0} \neq 0, \alpha_{1}=0, \beta_{0} \neq 0, \beta_{1}=0$ ) is given by

$$
\begin{equation*}
\sum_{i=1}^{n} K_{i, j} a_{i}=F_{j}, j=1,2, \cdots, n \tag{7a}
\end{equation*}
$$

where $K_{i, j}=\int_{0}^{1}\left[\tilde{p}(x) \frac{d p_{i}}{d x} \frac{d p_{j}}{d x}+\tilde{q}(x) p_{i}(x) p_{j}(x)\right] d x, i, j=1,2, \cdots, n$
$F_{j}=\int_{0}^{1}\left[\tilde{r}(x) p_{j}(x)-\tilde{p}(x) \frac{d \theta_{0}}{d x} \frac{d p_{j}}{d x}+\tilde{q}(x) \theta_{0}(x) p_{j}(x)\right] d x, j=1,2, \cdots n$
Case 3: The approximate solution of the differential equation (1a) consisting of Neumann boundary conditions (i.e., $\alpha_{0}=0, \alpha_{1} \neq 0, \beta_{0}=0, \beta_{1} \neq 0$ ) is given by
$\sum_{i=1}^{n} K_{i, j} a_{i}=F_{j}, j=1,2, \cdots, n$
where $K_{i, j}=\int_{0}^{1}\left[\tilde{p}(x) \frac{d p_{i}}{d x} \frac{d p_{j}}{d x}+\tilde{q}(x) p_{i}(x) p_{j}(x)\right] d x, i, j=1,2, \cdots, n$
$F_{j}=\int_{0}^{1} \tilde{r}(x) p_{j}(x) d x+\frac{c_{2}(b-a) \tilde{p}(1) p_{j}(1)}{\beta_{1}}-\frac{c_{1}(b-a) \tilde{p}(0) p_{j}(0)}{\alpha_{1}}, j=1,2, \cdots, n$
Case 4(i): The approximate solution of the differential equation (1a) consisting of Cauchy boundary conditions (i.e., $\alpha_{1} \neq 0, \beta_{1}=0$ ) is given by

$$
\begin{equation*}
\sum_{i=1}^{n} K_{i, j} a_{i}=F_{j}, j=1,2, \cdots, n \tag{9a}
\end{equation*}
$$

where $K_{i, j}=\int_{0}^{1}\left[\tilde{p}(x) \frac{d p_{i}}{d x} \frac{d p_{j}}{d x}+\tilde{q}(x) p_{i}(x) p_{j}(x)\right] d x-\frac{\alpha_{0} \tilde{p}(0) p_{i}(0) p_{j}(0)}{\alpha_{1}}, i, j=1,2, \cdots, n$
$F_{j}=\int_{0}^{1}\left[\tilde{r}(x) p_{j}(x)-\tilde{p}(x) \frac{d \theta_{0}}{d x} \frac{d p_{j}}{d x}-\tilde{q}(x) \theta_{0}(x) p_{j}(x)\right] d x-\frac{c_{1} \tilde{p}(0) p_{j}(0)}{\alpha_{1}}+\frac{\alpha_{0} \tilde{p}(0) \theta_{0}(0) p_{j}(0)}{\alpha_{1}}$
Case 4(ii): The matrix formulation with the Cauchy boundary conditions (i.e., $\alpha_{1}=0, \beta_{1} \neq 0$ )
is given by

$$
\begin{equation*}
\sum_{i=1}^{n} K_{i, j} a_{i}=F_{j}, j=1,2, \cdots, n \tag{10a}
\end{equation*}
$$

where $K_{i, j}=\int_{0}^{1}\left[\tilde{p}(x) \frac{d p_{i}}{d x} \frac{d p_{j}}{d x}+\tilde{q}(x) p_{i}(x) p_{j}(x)\right] d x+\frac{\beta_{0} \tilde{p}(1) p_{i}(1) p_{j}(1)}{\beta_{1}}, i, j=1,2, \cdots, n$
$F_{j}=\int_{0}^{1}\left[\tilde{r}(x) p_{j}(x)-\tilde{p}(x) \frac{d \theta_{0}}{d x} \frac{d p_{j}}{d x}-\tilde{q}(x) \theta_{0}(x) p_{j}(x)\right] d x+\frac{c_{2} \tilde{p}(1) p_{j}(1)}{\beta_{1}}-\frac{\beta_{0} \tilde{p}(1) \theta_{0}(1) p_{j}(1)}{\beta_{1}}, j=1,2, \cdots n$
Similar calculation for nonlinear boundary value problems using the Legendre polynomials can be derived which will be discussed through numerical examples in next portion.

## IV. Numerical Examples

In this section, we explain four linear and two nonlinear boundary value problems which are available in the existing literatures, considering four types of boundary conditions to verify the effectiveness of the present formulations described in the previous sections. The convergence of each linear boundary value problem is calculated by

$$
E=\left|u_{n+1}(x)-u_{n}(x)\right|<\delta
$$

where $u_{n}(x)$ represents the approximate solution by the proposed method using $n$-th degree polynomial approximation. The convergence of nonlinear boundary value problem is assumed when the absolute error of two consecutive iterations is recorded below the convergence criterion $\delta$ such that

$$
\left|\begin{array}{cc}
\tilde{\sim}^{N+1} & \tilde{\sim}^{N} \\
u & -u
\end{array}\right|<\delta
$$

where N is the Newton's iteration number and $\delta$ varies from $10^{-8}$.
Example1. First we consider the boundary value problem with Robin boundary conditions [15]:
$-\frac{d^{2} u}{d x^{2}}+u=2 \cos x, \frac{\pi}{2}<x<\pi$
$u^{\prime}\left(\frac{\pi}{2}\right)+3 u\left(\frac{\pi}{2}\right)=-1, \quad u^{\prime}(\pi)+4 u(\pi)=-4$
The exact solution is $u(x)=\cos x$.
The boundary value problem (11) over $[0,1]$ is equivalent to the BVP

$$
\begin{aligned}
& -\frac{1}{\left(\frac{\pi}{2}\right)^{2}} \frac{d^{2} u}{d x^{2}}+u=2 \cos \left(\frac{\pi}{2} x+\frac{\pi}{2}\right), 0<x<1 \\
& \frac{2}{\pi} u^{\prime}(0)+3 u(0)=-1, \quad \frac{2}{\pi} u^{\prime}(1)+4 u(1)=-4
\end{aligned}
$$

Using the formula derived in Case-1, equation (6) and using different number of Legendre polynomials, the approximate solutions are shown in Table 1. It is observe that the accuracy is found nearly the order $10^{-5}, 10^{-6}, 10^{-6}, 10^{-7}$ on using $6,7,8$, and 9 Legendre polynomials respectively.

Example2. We consider the boundary value problem with Dirichlet boundary conditions [1]:
$\frac{d^{2} u}{d x^{2}}+u=x^{2} e^{-x}, 0<x<10$
$u(0)=0, u(10)=0$
The exact solution is: $\frac{1}{2} e^{-x}\left[1+2 x+x^{2}-e^{x} \cos x-2 e^{x}\left\{-\frac{\cot 10}{2}+\frac{121 \cos e c 10}{2 e^{10}}\right\} \sin x\right]$
The boundary value problem (12) is similar to the VBP

$$
\begin{equation*}
\frac{1}{100} \frac{d^{2} u}{d x^{2}}+u=100 x^{2} e^{-10 x}, \quad 0<x<1 \tag{13a}
\end{equation*}
$$

$$
\begin{equation*}
u(0)=u(1)=0 \tag{13b}
\end{equation*}
$$

Using the formula calculated in Case-2, equation (7), the approximate solutions are summarized in
Table 2. It is shown that the accuracy up to $3,5,6$ and 8 significant digits are obtained for $8,10,12$ and 15 Legendre polynomials respectively.

Example3. In this case we consider the boundary value problem with Neumann boundary conditions [2]:
$\frac{d^{2} u}{d x^{2}}+u=-1, \quad 0<x<1$
$u^{\prime}(0)=\frac{1-\cos 1}{\sin 1}, u^{\prime}(1)=\frac{1-\cos 1}{\sin 1}$
whose exact solution is, $u(x)=\cos x+\frac{1-\cos 1}{\sin 1} \sin x-1$.
Applying the formula derived in Case-3, equation (8), the approximate solutions, given in Table 3, are obtained on using 5, 7, 8 and 10 Legendre polynomials with the remarkable accuracy nearly the order of $10^{-11}$, $10^{-13}, 10^{-13}$ and $10^{-17}$. On the other hand, Ramadan et al. [6] has found nearly the accuracy of order $10^{-6}$ and $10^{-6}$, and $10^{-8}$ on using quadratic and cubic polynomial splines, and nonpolynomial spline respectively with $\mathrm{h}=1 / 128$ where $h=(b-a) / N, a$ and $b$ are the endpoints of the domain and $N$ is number of subdivision of intervals $[a, b]$.

Example4. We consider the Cauchy (mixed) boundary value problem [4]:
$\frac{d^{2} u}{d x^{2}}-3(u-25)=0,0 \leq x \leq 2$
with mixed boundary conditions
$u(0)=150($ Dirichlet $), u^{\prime}(2)=0($ Neumann $)$
whose exact solution is $u(x)=25+125 e^{-\sqrt{3} x}-\frac{125 e^{-\sqrt{3} x}}{1+e^{4 \sqrt{3}}}+\frac{125 e^{\sqrt{3} x}}{1+e^{4 \sqrt{3}}}$
Using the formula illustrated in Case-4(ii), equation (10), and using different number of Legendre polynomials, the approximate solutions are shown in Table 4. It is observe that the accuracy is found nearly the order $10^{-5}, 10^{-7}, 10^{-9}$ and $10^{-14}$ on using $8,10,12$, and 15 Legendre polynomials respectively.

We now also apply the procedure described in section 3, formulation of second order linear BVP, to find the numerical solutions of one nonlinear second order boundary value problem.

Example5. We consider a nonlinear BVP with Dirichlet boundary conditions [16]
$\frac{d^{2} u}{d x^{2}}+\frac{1}{8} u \frac{d u}{d x}=\left(4+\frac{1}{4} x^{3}\right), 1<x<3$
$u(1)=17$ and $u(3)=\frac{43}{3}$
The exact solution of the problem is given by $u(x)=x^{2}+\frac{16}{x}$

To implement the Legendre polynomials, first we convert the BVP (16) to an equivalent BVP on the interval $[0,1]$ by replacing $x$ by $2 x+1$ such that
$\frac{d^{2} u}{d x^{2}}+\frac{1}{4} u \frac{d u}{d x}=16+(2 x+1)^{3}, 0<x<1$
$u(0)=17$ and $u(1)=\frac{43}{3}$
Suppose that the approximate solution of the boundary value problem (17) applying the Legendre polynomials is given by
$\tilde{u}(x)=\theta_{0}(x)+\sum_{i=1}^{n} a_{i} p_{i}(x), n>1$
Where $\theta_{0}(x)=17-\frac{8 x}{3}$ is specified by the dirichlet boundary conditions at $x=0$ and $x=1$ and $p_{i}(0)=p_{i}(1)=0$ for each $i=1,2, \cdots, n$.

The weighted residual equations of (17a) corresponding to the approximation solution (18), given by
$\int_{0}^{1}\left(\frac{d^{2} \tilde{u}}{d x^{2}}+\frac{1}{4} \tilde{u} \frac{d \tilde{u}}{d x}-\left[16+(2 x+1)^{3}\right]\right) p_{k}(x) d x=0, k=1,2, \cdots, n$
Exploiting integration by parts with minor simplifications, we have

$$
\begin{align*}
& \sum_{i=1}^{n}\left[\int_{0}^{1}\left[-\frac{d p_{i}}{d x} \frac{d p_{k}}{d x}+\frac{1}{4}\left(\theta_{0} \frac{d p_{i}}{d x} p_{k}+\frac{d \theta_{0}}{d x} p_{i} p_{k}\right)+\frac{1}{4} \sum_{j=1}^{n} a_{j}\left(p_{i} \frac{d p_{j}}{d x} p_{k}\right)\right] d x\right] a_{i} \\
& =\int_{0}^{1}\left[\left(16+(2 x+1)^{3}\right) p_{k}+\frac{d \theta_{0}}{d x} \frac{d p_{k}}{d x}-\frac{1}{4} \theta_{0} \frac{d \theta_{0}}{d x} p_{k}\right] d x, k=1,2, \cdots, n \tag{20}
\end{align*}
$$

The above equation (20) is equivalent to the matrix form
$(D+C) A=G$
where the elements of the matrix $\mathrm{A}, \mathrm{C}, \mathrm{D}$ and G are $a_{i}, c_{i, k}, d_{i, k}$ and $g_{k}$ respectively, given by

$$
\begin{align*}
& d_{i, k}=\int_{0}^{1}\left[-\frac{d p_{i}}{d x} \frac{d p_{k}}{d x}+\frac{1}{4}\left(\theta_{0} \frac{d p_{i}}{d x} p_{k}+\frac{d \theta_{0}}{d x} p_{i} p_{k}\right)\right] d x  \tag{21b}\\
& c_{i, k}=\frac{1}{4} \sum_{j=1}^{n} a_{j} \int_{0}^{1}\left(p_{i} \frac{d p_{j}}{d x} p_{k}\right) d x  \tag{21c}\\
& g_{k}=\int_{0}^{1}\left[\left(16+(2 x+1)^{3}\right) p_{k}+\frac{d \theta_{0}}{d x} \frac{d p_{k}}{d x}-\frac{1}{4} \theta_{0} \frac{d \theta_{0}}{d x} p_{k}\right] d x, k=1,2, \cdots, n \tag{21d}
\end{align*}
$$

The initial values of these coefficients $a_{i}$ are obtained by applying the Galerkin method to the BVP neglecting the nonlinear term in (17a). Therefore, to find the initial coefficients, we will solve the system
$D A=G$
where the elements of the matrices are given by

$$
\begin{align*}
& d_{i, k}=-\int_{0}^{1} \frac{d p_{i}}{d x} \frac{d p_{k}}{d x} d x  \tag{22b}\\
& g_{k}=\int_{0}^{1}\left[\left(16+(2 x+1)^{3}\right) p_{k}+\frac{d \theta_{0}}{d x} \frac{d p_{k}}{d x}\right] d x, k=1,2, \cdots, n
\end{align*}
$$

Once the initial values of the parameters $a_{i}$ are obtained from equation (22a), they are substituted into equation (21a) to obtain new estimates for the values of $a_{i}$. This iteration process continues until the converged values of the unknowns are obtained. Putting the final values of coefficients into equation (18), we obtain an
approximate solution of the BVP (17), and if we replace x by $\frac{(x-1)}{2}$ in this solution we will get the approximate solution of the given BVP (16).
Using first 10 and 15 Legendre polynomials with 10 iterations, the absolute differences between exact and the approximate solutions are given in Table 5. It is observed that the accuracy is found of the order nearly $10^{-6}$ and $10^{-9}$ on using 10 and 15 Legendre polynomials respectively.

Table 5: Exact, approximate solutions and absolute differences of example 5 using 10 iterations

| x | Exact | Approximate | Error | Approximate | Error |

## V. Conclusions

In this paper, the formulation of one dimensional linear and nonlinear second order boundary value problems have been discussed in details by the Galerkin weighted residual method applying Legendre polynomials as the basis functions in the approximation. The proposed method is applied to solve some numerical examples both linear and nonlinear. The computed results are compared with the exact solutions and we have found a good agreement with the exact solution. All the mathematical formulations and numerical computations have been done by MATLAB-10 code.
